MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Aberystwyth Infirmary and Cardiganshire General Infirmary.—A case of unusual fracture of the clavicle (under the care of Mr. R. T. Edwards), 1201
Berkshire Royal Hospital, Reading.—Two cases of thrombosis (under the care of Dr. Francis H. Hawkins), 793
Birmingham Queen's Hospital.—A case of an uncommon form of spina bifida (under the care of Mr. W. Billington), 1053
Bristol Royal Infirmary.—A case of triple telescopic intussusception originating in Meckel's diverticulum (under the care of Mr. T. Carwardine), 505
Bulawayo Memorial Hospital.—(1) A case of interscapulo thoracic amputation; and (2) a case of Cæsarean section (under the care of Mr. W. G Clark), 366
Central London Ophthalmic Hospital.—Opitic neuritis, ocular paralysis, and absence of the knee jerks in a case of chlorosis (under the care of Mr. Ernest Clarke and Dr. C. O. Hawthorne), 1198
Devon and Exeter Royal Hospital.—A case of intracranial hæmatoma (under the care of Mr. J. Delpratt Harris), 1199—Two cases of actinomycosis (under the care of Mr. C. E. Bell and Mr. J. D. Harris), 1656
Devonport Royal Albert Hospital.—Perforated duodenal ulcer; operation; recovery (under the care of Dr Alonzo G. Rider), 1425
Durham County Hospital.—A case of double multilocular cyst of the ovaries (under the care of Dr. S. W. Plummer), 1351
East London Hospital for Children, Shadwell, E.—A case of diaphragmatic hernia (under the care of Dr. Eustace Smith), 1424
French Hospital.—Six consecutive cases of disease of the Fallopian tubes (under the care of Dr. S. Sunderland and Mr. Edmund Owen), 991
Government Civil Hospital, Hong Kong.—A case of double amputation; recovery (under the care of Mr. E. A. R. Laing), 95—A case of ruptured spleen presenting features of unusual medico-legal interest; splenectomy; death (under the care of Mr. E. A. R. Laing), 1122
Great Northern Central Hospital.—A case of sarcoma of the pleura and lung with consecutive pericarditis and growth in brain and pancreas, presenting unusual clinical features (under the care of Dr. H. W. Syers), 1651
Hillingdon Cottage Hospital.—A case of tetanus treated by the injection of antitoxin (under the care of Dr. A. Charpentier), 1722
Leeds General Infirmary.—A case in which a gall stone was removed from the gall-bladder; subsequent development of malignant disease of the gall-bladder; death from suppurative cholangitis (under the care of Mr. R. Lawford Knaggs), 1054
Lincoln County Hospital.—A case of total paraplegia due to caries of the middle dorsal vertebræ; costo-transversectomy; complete recovery (under the care of Dr. W. H. B. Brook), 505
Liverpool Infirmary for Children.—Four [illegible] inguinal hernia in [illegible] five weeks, four [illegible] (under the care of Mr. R. C Dun) 1591
Liverpool Mill-road Infirmary.—Two cases of tubal gestation; rupture; abdominal section; recovery (under the care of Dr. Nathan Raw), 297
Liverpool Royal Southern Hospital.—A case of spontaneous perforation of the intrapericardial portion of the inferior vena cava (under the care of Mr. I. McW. Bourke), 723
London Hospital.—23 consecutive cases of operation upon the stomach (under the care of Mr. C. W. Mansell Moullin), 92
Manchester, Royal Infirmary.—A case of cicatricial pyloric obstruction; pyloroplasty; hæmatemesis from a second ulcer; operation; recovery (under the care of Mr. G. A. Wright and Mr. J. E Platt), 1122
Mexborough Montague Cottage Hospital.—A case of pyloric stenosis and gastric dilatation of very long duration (21 years); posteri[illegible] complete recovery [illegible] B. Crossfield Stevens), [illegible]
Middlesex Hospital.—A case of foreign body impacted in the left bronchus; removal by operation (under the care of Dr. W. Pasteur and Mr. T. H. Kellock), 795
Nablus Hospital, Palestine.—A case of closure of the jaws due to cicatricial bands (under the care of Dr. J Cropper), 653
Newcastle-upon-Tyne Royal Infirmary.—Cases in which death occurred after exploratory puncture of the chest (under the care of Dr. Thomas Oliver), 26—A case of Jacksonian epilepsy; trephining; temporary recovery; death from acute œdema of the brain (under the care of Dr. Thomas Oliver and Mr. W. G. Richardson), 1795
Pretoria Hospital.—A case of recovery after operation for perforation in enteric fever (under the care of Dr George Thornton and Dr. A. W. Sanders), 1723
Rochdale Infirmary.—A case of gastrostomy for stricture of the œsophagus (under the care of Mr. Wm. Pooley), 1722
Royal Free Hospital.—A case of repeated intestinal obstruction following an operation for removal of a cyst of the pelvis; recovery (under the care of Dr. T. C. Hayes and Mr. T. P. Legg), 1500
St. Bartholomew's Hospital.—A case of vertigo due to labyrinthine caries; operation on the labyrinth; complete recovery (under the care of Mr. A. E. Cumberbatch and Mr. C. Ernest West), 1570
St. George's Hospital.—Conservative operation in a case of acute suppurative salpingitis (under the care of Mr. Herbert W. Allingham), 25—Three cases of prostatectomy (under the care of Mr. H. W. Allingham), 1279
St. Mary's Hospital.—A case of septicæmia with interesting complications (under the care of Dr. W. B Cheadle), 653—A case of hernia cerebri following compound depressed fracture of the skull; removal on two separate occasions; recovery (under the care of Mr. A Q Silcock), 868
St Thomas's Hospital.—Seven cases of intestinal obstruction (under the care of Mr. G. H. Makins, C.B), 156
Salop Infirmary, Shrewsbury.—A fatal case of Raynaud's disease (under the care of Dr. Edward Cureton), 1349
Seamen's Hospital, Las Palmas, Canary Islands.—A case of enterectomy for gangrenous hernia (under the care of Dr. J. Cleasby Taylor and Dr. Rafael Gonzalez y Hernandez), 1055
Sunderland Infirmary.—An unusual sequence of hernial troubles in an infant; operations; recovery (under the care of Dr. Stanley Raw), 225
Sussex County Hospital.—A case of central gliomatosis of the spinal cord; complete paraplegia; normal delivery after induced labour (under the care of Mr. T. H. Ionides and Dr. E. Hobhouse), 1795
University College Hospital.—A case of longitudinal fracture of the tibia (under the care of Mr. Rickman J Godlee), 504—A case of tetanus treated with antitetanic serum; recovery (under the care of Dr. J. Rose Bradford), 934
Westminster Hospital.—Five cases of ulcerative colitis (under the care of Dr. W. Murrell), 721
Worcester General Infirmary.—A case of chronic intussusception due to multiple polypi of the intestine (under the care of Dr. Mabyn Read), 797

LIST OF ILLUSTRATIONS.

Four Drawings accompanying paper on Some Simple Expedients in Physical Therapeutics (Dr. W. Essex Wynter), 11, 12

Four Microphotographs of the Tympanic Bullæ and Vertical Sections of the Eustachian Tubes in Dogs, accompanying paper on Deafness and Middle ear Disease, 86, 87

Photoprint showing Abdominal Wall accompanying paper by Mr. E. Stanmore Bishop on Chronic Abdominal Surgical Disease, 142

Diagram showing Frequency of Granular Kidneys in proportion to Healthy Kidneys accompanying paper by Dr. Samuel West; 145

Picture of Dorsal Aspect of a Penis in a case of Hypospadias, 146; Vulva of a Human Fœtus in the Seventh Month, and Side View of the Penis and Scrotum of a child at Full Time, 147; illustrating a paper on Preputial or Odoriferous Glands of Man.

Diagram showing Marrow Cells, Phagocytes and several Isolated Bodies from the Marrow and Spleen accompanying paper on the Question of Trypanosoma Infection in Man, 149

Temperature Chart illustrating case of Lobar Pneumonia (Dr. J. M. Bennion), 151

Three Charts accompanying paper on Atmospheric Temperature and *Small-pox (Dr. David Shrewright)*, 152

Chart showing Influence of Salicylates and Aspirin, and also of a Rigid Diet, on the Sugar Excretion in Diabetes accompanying paper by Dr. R. T. Williamson, 215

Thirteen Figures of Pipettes described in paper on Certain New Methods of Blood Examination (Dr. A. E. Wright), 216, 217

Two Full length *Portraits of Male and Female Figures accompanying* paper on two cases of Osteitis Deformans in one family (Dr. Walter J. Kilner), 221

Four Photoprints illustrating paper on Hysterical Skin Symptoms and Eruptions (Dr. Thomas D. Savill), 275, 276

Drawings of Tylenchus Obtusus accompanying paper on Infection by Filaria Perstans (Dr. H. Charlton Bastian), 287

Diagram showing Scheme of the Systemic and Pulmonary Circulation, accompanying paper on Cardiac Failure by Dr. A. Morison, 294

Ground Floor Plan and Photoprint of Osborne House Convalescent Home for Officers of the Navy and the Army, 321, 322

Perimeter Chart accompanying paper on the Eye Symptoms of Rheumatoid Arthritis (Mr. W. M. Beaumont), 368

Six Illustrations of the Three Types of Characteristic Mitoses in Adenocarcinoma accompanying paper by Dr. E F. Bashford and Dr. J. A. Murray, 413

Three Photoprints of Sequestra and one Photoprint of Temporal Bone accompanying paper on the Etiology and Treatment of Suppuration of the Labyrinth (Dr. W. Milligan), 417, 418

Three Microphotographs *of Filaria Perstans and one Microphotograph* of Filaria Demarquaii accompanying paper by Dr. G. C. Low, 420, 421

Portrait *showing* Iodide Rash in a Syphilitic Patient Resembling a Variolous Eruption, 421

Drawing showing Horizontal Section through Cochlea, Tympanum, and External Ear of Rat about fourth week accompanying paper on Latent or Intermittent Nasal Obstruction (Mr. Mayo Collier), 430

Reproduced Specimens of Handwriting of Patient Before and After Treatment by Hypnosis, 492

Drawing of Section through Left Shoulder-joint, looking towards Hand showing Anatomy of Parts concerned in Subspinous Dislocation of the Shoulder (Dr. Arthur Keith), 496

Diagrammatic Representation of Triple Telescopic Intussusception originating in Meckel's Diverticulum, 506

Diagram and Photoprint illustrating New Apparatus for Maintaining Artificial Respiration, 515

Illustration of New Anaerobic Apparatus, 515

Photoprints and Diagrams of Four Open Domestic Grates, 529, 530, 532

Four Smoke Charts of Four Grates, 531

Plotted Results of Tests on Grates, 532

Diagrams of Smoke Scale showing Degrees of Blackness of Smoke emitted by Grates, 534

Drawings accompanying Hunterian Lectures on the Evolution and Action of Certain Muscular Structures of the Heart (Dr. Arthur Keith), 555 to 558, 629 to 632, 703 to 707

Two Drawings accompanying Paper on Rupture of a Tubal Pregnancy (Dr. W. Duncan), 564, 565

Two Complete 24 hour Continuous Clinical Temperature Charts, 585

Illustration of Uterine "Flag Mop," 586

Photoprint showing New Spectacle Frames for Ptosis, 586

Illustrations of the New Science Schools at Cambridge University, 59 to 603

Photoprint of the Sedgwick Statue at Cambridge, 604

Five Portraits of Patients accompanying Paper on Motor Symptoms of Mania and Melancholia (Dr. W H. B. Stoddart), 639, 640

Portrait of the late Sir Edward Henry Sieveking, M.D. Edin., F.R.C.P. Lond., 681

Four Diagrams accompanying paper on the Congenital Origin of Hernia (Mr R. Hamilton Russell), 708, 709

One Skiagram and One Photoprint accompanying paper on the Ambulatory Treatment of *Fractures of the Lower Extremity by* Hoefftcke's Modified Hessing's Splint Case Appliance (Mr. T. H. Openshaw), 711

Temperature Chart in a case of Metritis and Cellulitis in the *Puerperium treated with Antistreptococcic Serum (Dr. John W.* Duncan), 720

Multiple Stethoscope designed by Dr. W. G. Aitchison, 731

Improved Operation Table designed by Mr. J. Lionel *Stretton*, 731

The Cavendish Lecture

ON

EXPERIMENTS ON THE IMMUNISATION AGAINST INFECTION OF OPERATION WOUNDS, ESPECIALLY OF THE PERITONEUM.

Delivered before the West London Medico-Chirurgical Society on June 24th, 1904,

BY JOHANN VON MIKULICZ-RADECKI,
M.D., LL.D.,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF BRESLAU.

MR. PRESIDENT AND GENTLEMEN,—The successful treatment of infectious diseases to-day involves in many cases a combination of the two methods of treatment discovered, *the one by Edward Jenner and the other by Lord* Lister. Hygienic measures based upon Listerian principles keep the cause of infection at a distance, or at least make it harmless before it can come into contact with the human organism, whilst specific preventive inoculation has for its object the rendering of individuals more capable of resisting infection. Surgery has made but little use of the principle of preventive inoculation because the multitude of variety of pyogenic micro-organisms which may infect the wound adds greatly to the difficulty of finding a practical method of inoculating against them. Another reason why the question of immunisation *of wounds* has not advanced is that there is not so great practical necessity as in the case of general infectious diseases because the majority of wounds are efficiently guarded from infection by antiseptic treatment. There are, however, many operations and wounds in which the principle of antisepsis becomes useless because the a[illegible] to their physiological propert[illegible] tions, are invaded by pathog[illegible] of effectually disinfecting the mucous membrane of the stomach and intestines in preparation for operation has not yet been solved. We possess, it is true, a number of technical expedients for limiting the danger of infection but they do not succeed with certainty in preventing it in every case. The dangerous peritonitis in serious operations on the stomach and intestines is due to the fact that the bacilli f[illegible] eat a number to be tolerate[illegible] o say, the natural power [illegible] in the individual is not sufficient to overpower the mass of bacteria introduced. We can only diminish the danger of peritonitis at the present time by increasing the power of resistance of the peritoneum against intestinal bacteria. One means of effecting this is by producing an artificial [illegible] Loewy and Richter were [illegible] of albumoses, especially spermin. [illegible] thereby [illegible] pneumo[illegible] subcutaneous injection of albumose into rabbits made them proof against pneumococci and mouse septicæmia. After *each injection a hypoleucocytosis occurred first* and later a hyperleucocytosis. If the infection was brought about during hypoleucocytosis the animals without exception died. On the other hand, the course of the disease was influenced in the most favourable way when the infection was introduced after a hyperleucocytosis had occurred and was still increasing. [illegible] that during the stage of hy[illegible] men and dogs possessed a higher bactericidal value than normal blood. Hahn used yeast nuclein in his experiments on dogs and tuberculin in those on man. These experiments do not seem to have led to any practical result in the case of man. At any [illegible] septicæmia by [illegible] of nuclein by [illegible] of artificial hy[illegible] made itself evident—as, for example, in pneumonia—can be readily understood. The infected organism is at the time of the application of the remedy overpowered by the pathogenic microbes; all the engines of defence of the organism have already had to be led into the field. A still further increase through a later artificial hyperleucocytosis cannot be expected.

The question arises whether artificial hyperleucocytosis may not be of value in practice as a prophylactic. According to the above-mentioned experiments of Loewy and Richter, of Jakob and Hahn, one cannot exclude the possibility that by a partly anticipated mobilisation of great masses of leucocytes the latter may overcome the bacteria which have obtained entrance in the first instance in relatively small masses with greater ease than if the leucocytes delay their attack in force until the number and virulence of the bacteria in the tissues have markedly increased. Whether the observations of Jakob are applicable to the peritoneum had to be established by experiments on animals before they could be used upon man. Dr. Miyake of Japan, who recently worked in my clinic, undertook at my suggestion these experiments upon animals. These were carried out in the Breslau Hygienic Institute under the control of Professor Flugge. In this department of work we must note that we already had a predecessor named Salieri who in 1902 carried out experiments to increase the resistance of the peritoneum against bacillus coli infection. For this object he used small quantities of normal saline solution and found that *he could increase the natural resistance in guinea-pigs by* sevenfold to sixteenfold. The experiment was made three times on man in cases of laparotomy in which Salieri injected from 30 to 60 cubic centimetres of saline solution into the abdominal cavity. Salieri believed that he obtained favourable results, but in my opinion the operations *carried out by him do not definitely demonstrate* an increased resistance of the peritoneum. Salieri was led to undertake his investigation by the well-known experiments against cholera conducted by Issaeff in 1894. Issaeff produced in g[illegible] in the peritoneal transudate by [illegible] of normal saline solution, of [illegible] and of tuberculin. At the summit of this hyperleucocytosis he injected virulent cholera vibrios into the peritoneum and noted, according to the nature of the injected fluid, a more or less marked increase in the resistance of the peritoneum to the injected cholera bacilli. The most powerful reaction was obtained with nucleic acid. With an injection of one cubic centimetre of a 2 per cent. solution of nucleic acid the peritoneum was able to withstand from 13 to 17 lethal doses of cholera vibrios. Issaeff observed that the destruction of the microbes was carried out by the leucocytes of the peritoneal transudate. After only two hours the phagocytosis was evident. In the third hour free micro-organisms could no longer be found in the exudate and after five hours the process of destruction of microbes was completed. Just as Iss[illegible] ments we too selected th[illegible] of a satisfactory specific [illegible] the virus of peritonitis, as has been explained, are extremely small, nevertheless we ma[illegible] first, for in guinea-pigs the [illegible] able. The bacilli coli alone [illegible] peritoneum of the guinea-pi[illegible] peritonitis in man, especially [illegible] coccus pyogenes, are almost [illegible] *The experiments were carri*[illegible] a loopful to two loopfuls of a sterilised culture were injected into the peritoneum from a strain of bacillus coli. After a definite interval, which was different in different experiments, had elapsed the animals tolerated the introduction of five loopfuls of living, virulent culture and also the escape of the contents of the intestine into the abdominal cavity. The active immunisation with a strain of bacillus coli (derived from man) was thus, we may presume, able to protect against other bacillus coli strains that were accidentally present in the contents of the intestine. Nevertheless, it is possible to come across by chance strains in the case of which this does not occur. That in man we have to reckon not only with *different strains of bacilli coli but also with* different strains of streptococci and other pathogenic bacteria has been demonstrated above. On these grounds we did not make any further [illegible] immunisation ever [illegible] consisted exclusiv[illegible] resistance by hyperleucocytosis. In accordance with the procedure of Issaeff we tried the injection of various fluids into the peritoneal cavity; later, subcutaneous injections were also tried, for this form of application is better adapted to man than that of intraperitoneal injections. Sodium chloride solution (0·85 per cent.), neutral bouillon (2 per cent.), starch in physiological salt solution, and nucleic acid were used for injection. The first three solutions were only used intraperitoneally, nucleic acid subcutaneously as well. For intraperitoneal injection 2 per cent. of nucleic acid was used, for subcutaneous injection 5 per cent., neutralised nucleic acid solution one cubic centimetre of the solution was injected per 250·330 grammes body-weight. We found, in agreement with earlier experimenters, that the intraperitoneal injections of normal saline solution in the quantities above mentioned gave rise to a marked hyperleucocytosis in the peritoneal transudate. The maximum was reached after from 17 to 18 hours with an increase to about fourfold the normal leucocytosis. Still greater was the effect when the peritoneal cavity was washed out with 50 cubic centimetres of normal saline solution; in this case about two-thirds of the solution was left in the cavity. Maximum hyperleucocytosis occurred after 24 hours and resulted in five times the normal number of leucocytes. The reaction due to neutral bouillon was much less marked than that of normal saline solution. But a far more energetic action followed the 2 per cent. aleuronat mucilage. The maximum peritoneal hyperleucocytosis occurred in 30 hours and rose to between seven and eight times the normal number. A similar result followed the use of nucleic acid but the reaction was more speedy. The maximum was between seven and eight times the normal and occurred eight hours after the injection. Along with the local general leucocytosis in the blood took place but to nothing like the same extent. The maximum in one case was double the normal number of white cells. Subcutaneous injection also of 5 per cent. nucleic acid led to a hyperleucocytosis in the peritoneum as well as in the blood. The latter reached almost to the same height as with the injection in the peritoneum, the former remained far below. It reached approximately two and a half times the normal number. The important point is that here also, as in the experiments of Jakob, the injection caused a hypo-leucocytosis in all cases after half an hour to one and a half hours. With normal saline solution and with bouillon it was not considerable; with aleuronat and nuclein it fell even to one-tenth of its original amount in the peritoneal transudate. No general disturbance of any importance occurred. With the injection of normal saline solution the temperature was scarcely raised; with aleuronat and nucleic acid there was a rise of from 0·5° to 1·5° during the first hours after the injection.

After these experiments we used the injection with the above-mentioned fluids as a preliminary to an infection of the peritoneum and in the first instance a strain of bacterium coli was employed which we found to be very virulent for guinea-pigs. After it had been ascertained by 11 test experiments that the minimum lethal dose was a quarter of a loopful, the prepared animals were infected with the same strain. The infection of the peritoneum followed regularly seven hours after the preparatory treatment and therefore at a time when the hyperleucocytosis had not yet quite reached the maximum. The result was as follows. The effect of a single injection into the peritoneum of one cubic centimetre of normal saline solution was relatively weak, the power of resistance being only doubled (the infection after washing out the peritoneum with saline solution could not be employed because the bacillus coli strain at the time of the experiments in question had already lost its virulence). Much more energetic was the action of the intraperitoneal injec[illegible] ...e it increased the resistance of [illegible] Nucleic acid was still more [illegible] power of resistance of the peri[illegible] 16 to 20 fold. The subcutaneous [illegible] neutralised nucleic acid similarly [illegible]sistance of the peritoneum from 16 [illegible]eaker was the action of a 0·25 per [illegible] of repeated intraperitoneal injec[illegible]as considerably stronger. In this [illegible] the peritoneum could be raised to 40 [illegible] [illegible]dal action upon the bacterium [illegible] would have [illegible]y desirable to carry out the same series of experiments against the other bacteria that collaborate in the production of peritonitis in man and, above all, against the streptococcus and staphylococcus aureus and albus. Unfortunately, we found, in agreement with other people's observations, that the streptococci and staphylococci isolated from patients in our clinic were non-virulent for guinea-pigs. We therefore tried experiments upon rabbits but the same difficulty arose. It is not easy to find a strain of staphylococci which has a pathogenic effect on the peritoneum of the rabbit. We can definitely assume from the previously mentioned experiments of Kisskalt that in combating the staphylococcus pyogenes both leucocytosis and the destruction of the bacteria by the method of phagocytosis play at least as important a part as when the fight is between the organism and the bacterium coli. So far as the streptococcus is concerned the strains isolated from our clinic were insufficiently virulent for the peritoneum of the rabbit. One of the strains of the streptococcus given to us by Dr. Aronson of Berlin was, it is true, virulent for rabbits but to such a great extent that it acted as a specific bacterium of these animals. Against these highly virulent specific bacteria little effect is, as we already know, produced by a general increase of resistance by [illegible] these cases only a specific immunisati[illegible] infection. For these reasons the experiments could not be carried out in the way referred to. On the other hand, the experiments upon bacilli coli were supplemented in a most satisfactory manner by a series of observations which simulated the natural conditions occurring in peritonitis due to perforation. The experiments consisted in performing a laparotomy and forcing through an opening in the stomach or intestine as much of their contents as could be obtained from the immediate neighbourhood of the incision. Of five control animals which had not been previously prepared four died from peritonitis between five and 16 hours after the operation. The fifth became extremely ill but finally recovered but the amount of intestinal contents which was transferred to the peritoneum was less in this case than in the others. Ten animals were prepared. These recovered without exception. The preparation consisted in three intraperitoneal injections of nucleic acid, two injections of sterilised bacteria coli, three more injections of nucleic acid into the peritoneum, and two subcutaneous injections of neutralised nucleic acid. In each case laparotomy was performed seven hours after the injection. These experiments are such as to excite our interest in the highest degree, for by subcutaneous injections of nucleic acid it was possible to raise the resistance of the peritoneum to such an extent that even a considerable quantity of intestinal contents could be placed in the peritoneal cavity without causing damage, whilst without previous treatment an acute, rapidly fatal peritonitis followed almost without exception. This opens out a new field for the surgeon in preventing post-operative peritonitis. On three more animals a therapeutic experiment with neutralised 2 per cent. nucleic acid was tried. This solution was injected subcutaneously some time after the injection of the peritoneum with bacilli coli. It was found that when the infection had preceded the injection by six hours the peritoneum was able to stand only four times the lethal dose; whilst if the infection had taken place only one and a half hours before then the animal was able to withstand eight times the lethal dose. One animal which received 12 times the fatal dose along with the nucleic acid injection succumbed 19 hours after the infection. It therefore follows that subcutaneous injection of nucleic acid, if not used at too great an interval after the peritoneal infection, possesses a definite therapeutic value. This observation may perhaps be of value in acute cases of peritonitis from perforation.

Dr. Miyake has in three cases studied in detail the process of phagocytosis in the peritoneal exudate after the injection of bacillus coli. In two of these cases he employed preventive injections of nucleic acid into the peritoneum and in the third he used the drug subcutaneously. In all three cases an extremely active phagocytosis made itself evident half an hour after the infection. The number of microbes (in subcutaneous injection of nucleic acid) after half an hour was one-third, after one hour one-sixth, after three hours one-eighteenth, and after four hours one-hundred-and-eighth of the original number, whilst in the control animals the number of bacteria steadily increased. After 20 hours the exudate was sterile. The bacilli coli which still remained at the end of each interval of time proved on examination to be virulent in every case.

The action of the leucocyte could be very prettily watched in a microscopic preparation.

I felt justified after these promising experiments upon animals in beginning similar experiments, safeguarded by every precaution, upon man. The neutralised nucleic acid seemed to be the most suitable of the reagents which had been tried in the experiments upon animals. We first tried a ½ per cent. solution and gradually increased the strength up to 4 per cent. As a rule 50 cubic centimetres of the solution were injected subcutaneously. The injection was made under the skin of the chest in all cases with the exception of four; in these cases the upper part of the thigh was selected but owing to the inconvenient local pain this part of the body was not afterwards used. Intraperitoneal injection was tried in one case, and that the very first, but this method was entirely relinquished owing to its difficulty and the trouble it gave the patient. The 4 per cent. solution was injected twice. We altered this concentration because of the unpleasant general symptoms that were produced, for on both occasions it caused malaise and on one occasion sickness. There did not appear to be any reason, judging from the experiments on animals, for using so concentrated a solution. Thenceforth we always used the 2 per cent. solution, so that an adult man received about one gramme of nucleic acid to 75 kilogrammes of body weight, the same proportion approximately as we had tried in experiments upon animals. 58 cases in all were treated in this way between Jan. 7th and the middle of May. In 55 cases the operations were upon the stomach, intestine, or other abdominal viscera, and in three cases for extra-abdominal disease. In four cases the operations had, for some extraneous reasons, to be postponed, so that they did not take place until more than 34 hours after the injection was given. We have thus on four occasions had the opportunity of observing the effect of the injection by itself. This was the more welcome to us because we have learnt from investigations made by others that every operation, or even a simple anæsthesia, may give [illegible] therefore does not permit of [illegible] due to the injection of nucle[illegible] circumstance, and also our few clinical observations, enable us now to answer a number of questions on points about which we should like to have exact knowledge in reference to the working of this process in man. The following are the statements which I am now able to make. After the subcutaneous injection of neutralised nucleic acid we have constantly observed, not only in animals but also in man, a hyperleucocytosis in the blood which was almost always preceded during the first hour or so by a hypoleucocytosis. The question how high a degree of hyperleucocytosis was obtained through the injection is difficult to answer on the basis of our observations. To the earlier difficulties already referred to yet another must be added. Many of the patients showed a well-marked hyperleucocytosis even before the injection; for instance, in most cases of carcinoma of the stomach and in a few cases of cholelithiasis. It is clear that in these cases the relative increase of leucocytes cannot be so marked as in those cases where the number of leucocytes was normal. The highest value was 31,000 and the lowest 6100. Expressed in percentage with reference to the original number of leucocytes the increase of leucocytes in the blood varied from 9 to 452 per cent. In most cases we could not say whether the leucocytosis due to the injection of the nucleic acid had reached its maximum before the operation, for after the operation one could not with certainty assign a further rise to the nucleic acid. I am also convinced that where only a slight increase was observed this occurred after the operation and independently of it. We must admit this possibility because of the fact that, in the case of the four who were not operated upon during the first 34 hours, the maximum leucocytosis was on one occasion observed 24 hours after the injection. For the afore-mentioned reasons we are not in a position to make any definite statements as to the beginning of the most favourable phase of hyperleucocytosis because the operation was, in the great majority of cases, apparently performed before the commencement of this phase. Only in five cases was there a distinct [illegible] operation; in one of [illegible] fter the injection. [illegible] es from five to six [illegible], and in 12 cases from 13 to 19 hours after the injections. The experiments on guinea-pigs showed that the optimum for nucleic acid was reached seven hours after the injection. It seems to occur in man considerably later. We have therefore recently fixed the interval between preventive injection and operation at 12 hours. We believe that we thus, as a rule, follow out the instructions to operate on the rising tide of leucocytosis.

As regards the phenomena accompanying the injection of nucleic acid no serious local or general symptoms have as yet come under our observation. In the two cases in which a 4 per cent. solution had been injected the sensation of giddiness lasted but a short time. The most unpleasant factor for the patient is the local reaction. A tenderness and a slight swelling around the point of injection remain as a rule throughout the day. An intense erysipelas-like redness in two cases was seen, and it disappeared without leaving any trace after 24 hours. The only sign of reaction which appears with regularity is a slight increase in the temperature, which may be observed during the first few hours after injection (99° to 100°). In five cases the temperature remained below 98·6°, in 27 cases it rose to 100°, in six cases to 101°, in three cases to 102°, and in three cases above 102°. The rise in temperature was only in six cases accompanied by slight rigor, and even this was of short duration. The urine showed no pathological constituents after the injection and the patient's general condition was not in any other way impaired. Even the patients whose temperatures had risen suffered no discomfort thereby and maintained good appetites.

You will now ask me how far the immediate object of the injection of nucleic acid was attained, and how far the preparation of the cases had a favourable effect upon the course of the operation. The number of my experiments is not sufficient to permit me to form a definite judgment upon these points and to give an unguarded reply. We cannot in the case of man, as we do in that of the lower animals when introducing infective material into the abdominal cavity, give a certain multiple of the minimum lethal dose in order to see how far a preventive treatment has succeeded. We set all our apparatus in action, in spite of preventive inoculation, to reduce infection to the minimum. Since this method fortunately succeeds in the majority of cases, even without preventive inoculation, in guarding the patients from a fatal peritonitis a small number of satisfactory results do not prove much; but, on the other hand, one or two unsatistory results most certainly cannot condemn the method, for this method gives no absolute certainty like a specific immunisation but only increases the natural immunity and this may in certain circumstances, even when increased to thirty-fold, nevertheless be insufficient. I have, however, the impression that the cases hitherto treated have given more favourable results, not only in the number of cases that recovered but also in the progress of the individual cases, than the analogous cases of earlier date where the operation was performed without this preparation. In ten cases of resection of the stomach for carcinoma nine recovered, six of them without the slightest complication. The progress was marked by a smoothness that was quite exceptional before this treatment was adopted. Two cases which presented exceptional difficulty in the removal of the carcinoma did undoubtedly within 24 hours develop peritonitis with a pulse up to 160, which according to our usual experience foretold the most dismal prognosis. The patients fortunately survived this peritonitis. In the ninth case which recovered the progress was disturbed from the fourth day by broncho-pneumonia. The tenth case died; after seven days of uninterrupted progress he developed pneumonia to which he succumbed three weeks after the operation. Of the remaining operations I should like to refer first to 22 cases of gastro-enterostomy and entero-anastomosis, 12 of which were for carcinoma. Of these cases 19 recovered and three died. In all three cases death was most certainly not due to post-operative peritonitis, but in one case to perforation of an ulcerated carcinoma of the stomach two weeks after the operation, in another case to continued hæmorrhage from a carcinoma of the stomach 16 days after the operation, and in the third to peritonitis arising from a tuberculous granuloma in the intestine four weeks after operation. Of six cases of resection of the intestines at one operation four recovered and two died. In one case death occurred from collapse on the second day after a very prolonged operation of double resection for carcinoma; in the other case, where the injury was a bullet wound, death took place on the tenth day from hæmorrhage from the vena cava. In neither of the cases was there any peritonitis. One case of opening the stomach and stretching the cardiac orifice, performed on account of spasm, recovered. So also did six cases of operation on the bile-duct, seven other operations upon abdominal organs without opening the intestinal tract, and three extra-abdominal operations. The last to be mentioned are two cases of nephrectomy which were treated before the operation with nucleic acid. In both cases in order to remove the suppurating kidney the peritoneum had to be widely opened. One case recovered; the other died 12 days after the operation from hæmorrhage from the renal artery. In this case, too, there was no peritonitis. We therefore have 45 laparotomies in which the abdominal cavity was exposed to infection by the contents of the stomach or intestines or by some other infectious secretion. 38 of these cases recovered and in none of the seven fatal results was peritonitis the cause of death.

While relating my clinical experiences I have referred to nucleic acid only as a method of producing leucocytosis, but we have also used in most cases, and especially in severe operations upon the stomach and intestines, a second means which, according to experimental observations, is able to increase considerably the power of resistance of the peritoneum—I mean the intraperitoneal infusion of normal saline solution. Departing from my earlier practice I have used more and more during the last two years free irrigation of the peritoneal cavity with warm normal saline solution in all laparotomies in which the peritoneum runs some risk of infection.

The Milroy Lectures

ON

DEATHS IN CHILDBED: A PREVENTABLE MORTALITY.

Delivered before the Royal College of Physicians of London on Feb. 25th and March 1st and 3rd, 1904,

BY W. WILLIAMS, M.A., M.D., D.P.H. OXON.,

MEDICAL OFFICER OF HEALTH TO THE GLAMORGAN COUNTY COUNCIL.

LECTURE II.[1]

Delivered on March 1st.

THE ETIOLOGY OF PUERPERAL FEVER.

MR. PRESIDENT AND GENTLEMEN,—Puerperal fever has been common to lying-in women in all ages and climates and is described by Hippocrates 430 B.C., the first writer on the art of healing. Hippocrates, who contributed excellent clinical histories of the disease, did not only consider it as a dangerous disease but as a mortal one.

> "Morbus hic lethalis, et paucæ effugere possunt;
> Si mulieri pregnanti fiat in utero erysipelas, lethale est,"

and such were the views expressed by Celsus and Galen. Arabian physicians, such as Avicenna, as well as the physicians of the Middle Ages, have nothing more to say than that women in childbed sometimes took fever which led to their death. The medical writers of the sixteenth and seventeenth centuries go rather more into particulars. According to Hirsch it was Willis who first looked upon it as a disease which was different from other febrile processes, and he gave it the name of "febris puerperarum," and he went so far as to connect its origin with laceration of the uterus during labour and to refer it to a "miasma venenatum." By one writer the obstetric art was described as "only fit for fools and old women," and it was practised by them mostly until the establishment of a College of Physicians in London in 1518. In 1560 Thomas Raynold published his "Byrth of Mankinde." From the time of Thomas Raynold to that of Ströther, who wrote in 1716 and first termed it puerperal fever, many eminent men have written about puerperal fever, but their views differed but little from those of former writers. Thomas Cooper (1766) looked upon the disease as a truly dangerous and perplexing malady and considered that it proceeded generally from violent affections of the mind, such as grief, despondency, and the like.

With the exception of the statement that the disease was epidemic at Thasos in the time of Hippocrates the earliest epidemiological notice is one relating to the Hôtel Dieu of Paris in 1746, when it is said that of 20 patients who were seized with the disease scarcely one escaped. It is also pointed out that the hospital was crowded with patients at the time, an unusually large number of them being cases of wounds, and the ventilation of the wards was extremely defective and it is expressly stated that the lying-in department was directly over the wards occupied by the surgical cases. In 1830 Cruveilhier writes to the same effect on the epidemic of the Paris Maternité.

Hulme (1772) declared that the disease should be equally dreaded with the plague itself but did not consider it infectious. Denman (1788), according to Hirsch, was the first to allege that childbed fever was sometimes carried by medical men and midwives who had been in attendance on puerperal fever patients to other lying-in women.

In 1779-82 puerperal fever prevailed in an epidemic form at Aberdeen.[2] We are told in connexion with this epidemic that it prevailed principally among the lower classes of women but that women in the higher walks of life were not exempted; that it extended to the suburbs and contiguous country, where it proved as fatal as in the heart of the city. About 80 cases were attended by Gordon himself. To use his own words: "This disease seized such women only as were delivered or visited by a practitioner, or taken care of by a nurse, who had previously attended patients with the disease. In short, I had evident proof of its infectious nature and that the infection was as readily communicated as that of small-pox or measles and operated more speedily than any other infection with which I am acquainted." The infection was carried by a midwife to the country parishes of Nigg and Fintray and there also spread alarmingly.

The fever was epidemic in Leeds and its vicinity in 1809-12 and William Hey, jun., in his treatise on the epidemic tell us that it prevailed principally among the poorer classes of women but in the beginning it affected chiefly those in the higher stations of life and in its progress they were equally liable to its attacks. Its origin and spread could not be traced to any climatic conditions and it prevailed equally in both hot and cold weather. Dr. Hey writes: "It is somewhat remarkable that I have scarcely known an instance, in my own practice, of this disease coming on after præternatural delivery, or even a particularly hard labour. I do not mean to imply that such cases were more exempt from it than others, but so it has happened; and the fact shows that it was independent of anything untoward in the labour. It has, on the contrary, most frequently occurred, within the compass of my experience, after the most easy and most natural labour." This is entirely in accord with my own observations. I have known a medical man to go straight from a puerperal fever case to a confinement where the operation of turning was necessary. He introduced his hand into the uterus and the patient made a good recovery and was not infected with puerperal fever.

Armstrong (1813-14), in his description of the epidemic in Northumberland, Durham, &c., writes: "It is a singular fact that in whatever place the fever in question occurred it was principally limited to the practice of one accoucheur in the place." He further remarks: "This complaint, as it was presented to me, generally occurred about 24 to 30 hours after delivery. It did not seem to depend upon any difficulty of labour for in most of the women in whom it occurred parturition was remarkably easy. The first case at Sunderland occurred in January, 1813, and by the spring of the same year the disease had assumed formidable proportions." 43 cases occurred from Jan. 1st to Oct. 1st and of these 40 were treated by one medical man or his assistant, the remainder having been seen by three different accoucheurs. At Chester-le-Street, about nine miles from Sunderland, several cases occurred to a certain medical man, whilst a Mr. "N." of the same place only met with a solitary instance now and again. One accoucheur lost seven patients in a town not far from Newcastle-on-Tyne, and it is stated that the disease was confined to the patients of that practitioner and in the preceding year in like manner to those of one midwife in Newcastle itself. In May, 1813, the disease appeared at Alnwick and was confined to the practice of two medical men. Though one midwife who had a considerable increase of business had not a single case of the disease. another midwife, however, who had been about two days in the house of a lady dying from puerperal fever, went into a district about eight miles away and there delivered several women, nearly the whole of whom were attacked by puerperal fever. In this particular the epidemic strikingly corresponded with that of Dr. Gordon in Aberdeen; for he distinctly mentions that the disease occurred to certain individuals, whilst it was entirely unknown in the practice of others living in the same neighbourhood and he naturally attempted to account for this singular circumstance that the practitioner conveyed the contagion from patient to patient. The fever existed for more than two years in different parts of Durham and Northumberland. The epidemic really commenced in the neighbourhood of Stockton-on-Tees in 1811 and it spread to Newcastle-on-Tyne and Sunderland, afterwards to Chester-le-Street, and lastly in and about Alnwick. During its prevalence a great number of women died from the disease, but the number is not given and Dr. Armstrong says, "and this I was creditably informed, every patient perished who was not bled in the beginning."

---

[1] Lecture I. was published in THE LANCET of June 18th (p. 1701) and 25th (p. 1772).

[2] Gordon's Essay on Puerperal Fever at Aberdeen.

Armstrong was of opinion that puerperal fever was different from "the weed," "after pains," and "hysterites." The symptoms are very well described by him: "Abdominal pain or soreness, anxious breathing, unusual frequency of pulse, increased temperature, anorexia, prostration of the vital and voluntary powers, with an unnatural condition of the excrements are among the chief of the pathognomonic signs of the puerperal fever." It is well known that unmarried women do not recover so well as married women, the mental irritation attendant upon their condition considerably increasing the febrile excitement and thus accompanying the danger. Armstrong dealing with prevention says: "When puerperal fever is epidemic the accoucheur should make it a point of duty to have the apartment of the woman whom he is engaged to attend properly cleaned and ventilated before confinement; to prevent nurses and other persons who have been in contact with those affected from waiting upon or going near any patient about to be delivered; to pay the most scrupulous regard to the cleanliness of his own person, using daily ablutions of the wi[illegible]" [illegible] years on 20[illegible] Hospital, London (Table XXIII.). He classifies puerperal fever into four groups, the fourth of which is most dangerous, and he observes: "When this fourth form of puerperal fever is prevalent and characteristic of the epidemic 1 in every 3 dies in the London hospitals under any treatment and if the complications be many this mortality will be still increased, and the most judicious and the most humane act is to shut up these receptacles forthwith." Such, indeed, was the experience of William Hunter who used to say of puerperal fever cases: "Treat them in what manner you will at least three out of every four will die." Such was the experience of those who witnessed its plague-like ravages in the continental hospitals and such was that of Ferguson who was of opinion that this form of puerperal fever existed in hospitals alone. Ferguson further observes: "I believe that the single chamber of the pauper is more wholesome than the spacious ward of the hospital patient; while in private practice, among the well-housed and well-nourished, the milder forms are the commonest." This was also the opinion shared by most others at that time.

It would be interesting to give other instances, such as those recorded by Storrs (1842) in connexion with the Doncaster epidemic; by Blackmore (1831) in reference to an epidemic at Plymouth; by Simpson (1851) in connexion with some fatal cases at Edinburgh; Litzmann (1841–42) in connexion with an epidemic at Halle; and by Martin (1856); Schulten (1859); Netten Radcliffe (1865) in connexion with the Crickhowell epidemic; and so on. All these point in the same direction and should serve to impress upon us that the question of personal responsibility cannot be too strongly urged upon midwives and medical men.

It was Semmelweiss (1846) who founded the doctrine of the septic nature of puerperal fever by observing the frequency with which it followed the exposure of puerperal women to cadaveric putrefaction. It was this observation of Semmelweiss and the analogies of puerperal and surgical fevers first pointed out by Simpson, together with the investigations of Pasteur, Davaine, Rindfleisch, Koch, and others on the part played by micro-organisms in disease that led up to Lord Lister's system of antiseptic surgery. According to Priestley[3] it was Stadfelt of Copenhagen (1865) [illegible] hod to puerperal uses in the [illegible] He used carbolic acid; but [illegible] corrosive sublimate as being a more efficacious germicide. Guided by the progress of antiseptic surgery a new departure was inaugurated in Germany and then commenced aseptic, as distinguished from antiseptic, midwifery. The antistreptococcic serum when further elaborated may become an important factor in the prevention as well as in the cure of puerperal fever.

I will now relate some of my experiences in connexion with epidemics of puerperal fever which I was fortunate enough to have the opportunity of investigating. I was appointed medical officer of health of Glamorgan in December, 1892, and arrived in time to investigate an epidemic of this malady which had been for some time raging in two adjoining valleys included in the Garw and Ogmore urban district and situated in the centre of our coalfields. The valleys in question run north and south and are typical Glamorgan mining valleys—long, crooked, deep, and narrow. Their higher parts are densely populated on both sides of the black and highly polluted streams that run through each of them. Most of the houses are newly built and 16 or 18 years ago there was only an occasional farmhouse to be seen. The ridges of mountains on either side rise to a height of from 800 to 1200 feet above the sea level. The population of the two valleys numbers some 14,000, consisting for the most part of colliers and their families, with some tradesmen and artisans to minister to their wants. The houses are built of good quarried stone and are dry and comfortable in the majority of cases. There

are but a few privies, most of the houses having been in recent years supplied with pans and syphons, and connected with the public sewers. The water-supply is good and plentiful. The incidents of the epidemic were briefly as follows.

Puerperal fever had been prevalent in this district for many years; it is said to have been endemic in the Garw Valley. The number of cases that were reported or came to the knowledge of the medical officer of health for the period 1889–March 1st, 1893, were in—

Year.	Number of cases.	Recovered.	Died.
1889	9	4	5
1890	10	7	3
1891	14	12	2
1892	16	8	8
1893 (Jan. 1st to March 1st)	18	10	8

so that during January and February, 1893, 18 cases occurred and eight proved fatal. In 1892 the number of cases was 16, with eight deaths; in 1891 14 cases with two deaths; in 1890, ten cases with three deaths; and in 1889, nine cases with five deaths; making, in four years and two months, 67 cases, with 41 recoveries and 26 deaths. From Jan. 1st, 1892, to March 1st, 1893, 34 cases occurred; of the 26 in the Garw Valley, 12 were fatal; and of the eight in the Ogmore Valley, four were fatal. During this period (14 months) there were 793 births registered, showing a death-rate of 20·1 per 1000 registered births as compared with a mean rate of 2·5 for England and Wales. Table XXXV. shows the number of other infectious diseases that occurred in the district from 1889 to March 1st, 1893.

Of the 18 cases at Pontcymmer (Table XXXVI.) seven were primiparæ and five of them were fatal. Nine were attended by the same midwife and of these three were fatal. In six instances the drains were defective; in two the surroundings were insanitary.

Of the 11 cases at Blaengarw six were primiparæ, of whom four died. Four cases were attended by one midwife and four by another. Of the six that proved fatal all were natural and easy labours, and three, at least, were in young women. (Table XXXVII.)

TABLE XXXVII.—GIVING PARTICULARS OF CASES OF PUERPERAL FEVER AT BLAENGARW, IN THE GARW VALLEY, FOR A PERIOD OF TWO YEARS.

Initial of patient.	Date of confinement.	Primipara or multipara.	Midwife.	Duration of illness.	Results.	Remarks.
	1891.					
D.	March 3rd.	M.	Mrs. Ll.	3 weeks	R.	Miner's wife. House clean. Natural labour. Second day rigor and temperature 102° F. Third day temperature 104°. Severe abdominal pain and tenderness. Temperature normal on the twelfth day. Mrs. Ll. also attended another case at the same place, which also made a good recovery. Medical man present at the birth of the child.
G.	,, 8th.	M.	Mrs. T.	8 days.	D.	Natural labour. Rigor third day. No abdominal tenderness. Lochia sweet. Death eighth day. Temperature 108° F. No source of infection could be traced. House clean.
J.	Nov. 21st.	M.	Mrs. T.	2 weeks.	D.	Wife of grocer. House clean. Natural labour. Rigor seventh day. Temperature varied from 102° to 104° F., but at last went up to 107° a little before death. Cause of death, peritonitis.
	1892.					
M.	May 28th.	P.	Mrs. Ll.	4 weeks.	R.	Instruments used. Severe post-partum hæmorrhage. Rigor third day; temperature 105° F. same evening. Slight abdominal pain and tenderness. Discharge foul.
J.	Nov. 16th.	P.	Mrs. T.	7 days	D.	Age 23 years. Easy labour. Rigor second night. Temperature 103° F., with abdominal tenderness and cessation of lochia None of the usual sources of infection could be traced.
B.	,, 17th.	P.	Attended by a medical man.	7 days.	D.	Aged 21 years. Easy labour. Rigor second night and temperature of 102·5° F.; great tenderness over uterus and foul lochia although she had been washed with antiseptic lotions. This case was peculiar for its terrible and persistent vomiting. Her father, who lived in the same house, was then suffering from a large wound of the leg. House clean.
M.	Dec. 20th.	M.	Mrs. T.	—	R.	Forceps delivery. Rigor and high temperature on the fourth day which yielded to usual treatment.
M.	,, 24th.	P.	Mrs. Ll.	7 days.	D.	Easy labour. Age 20 years. Fifth day rigor, high temperature (104° F.), tympanites, and abdominal tenderness. Lochia, although profuse, were very foul; green vomiting. Died on the seventh day; hyperpyrexia. The midwife in this case had attended a fatal case about a fortnight before this one, but in the interval had, so she said, thoroughly washed and boiled all her clothes at the wish of a medical man.
H.	,, 30th.	M.	Mrs. R.	14 days.	R.	Forceps delivery. Rigor and high temperature on the third day. Temperature normal on the fifth day.
D.	,, 31st.	P.	Mrs. Ll.	14 days.	D.	Miner's wife. Natural labour. Progressed favourably till Jan. 7th, when she sat up in bed to nurse the child. Rigor following morning, with a temperature of 102° F. Great swelling and abdominal tenderness. Temperature 102°. Jan. 14th, temperature 107°. Death took place from peritonitis. House very clean. Slight post-partum hæmorrhage.
	1893.					
W.	March 4th	P.	Her mother.	—	R.	Easy labour. Rigor and high temperature on the second day. History of erysipelas in the same house 12 months previously.

The Nantymoel cases (Table XXXVIII.).—D. was confined in a house where the whole family, six in number, had suffered from scarlet fever. The last was convalescent at the time of her confinement. On the second day symptoms of puerperal septicæmia were developed with a high temperature and foul discharge. The uterus was washed with a solution of perchloride of mercury and in a week the patient was convalescent and made a good recovery. About six weeks afterwards E. was delivered of twins. There was a severe rigor on the second day accompanied by a high temperature. In a few days symptoms of peritonitis developed and the patient died on the eighth day. She was attended by H. L.

TABLE XXXVIII.—*Giving Particulars of Cases at Nantymoel and Tynewydd (almost adjoining), in the Ogmore Valley.*

J.	Jan. 8th.	—	,,	—	D.	—
H.	,, 21st.	—	,,	—	D.	Mrs. H. L. was stopped attending for nine weeks but had since attended six cases without ill effects.
I.	,, 27th.	—	Mrs. A. W.	—	R.	—
K.	,, 27th.	—	,,	—	R.	—

Three days after the death of E., F. was confined in the same street and attended by the same midwife (H. L.). A rigor occurred on the second day with signs of peritonitis on the third. She rapidly got worse and died on the sixth day. During the interval between the first and second cases (above recorded) H. L. attended several cases without any signs of septicæmia. After the third case she was debarred from attending for six weeks. At the end of six weeks she attended another case. This patient was very ill three days before her confinement and died three days after delivery from violent peritonitis. Four days afterwards H. L. attended another woman who made a good recovery in due time. This same midwife went on attending confinements for three weeks without any ill effects until she attended H. This patient had a rigor on the second day, with a temperature of 101° F. On the morning of the third day the temperature was 102°, and by 4 o'clock of the same day the temperature was 107°. She became unconscious and died at 7 o'clock the same evening. After the above case the midwife was debarred attending up to March, 1893.

During the same period of about five months, A., I., and K. were attended by A. W., another local midwife. All these recovered. This midwife had attended many cases since and without any ill effects. During the same period, and indeed during the year, several cases of confinement occurred and were attended by three different midwives, where a slight rise of temperature was manifested, but they recovered. Influenza was prevalent at the time. It was a very common occurrence in this practice to have slight cases of the so-called puerperal fever, but generally they were easily controlled by antipyretics and disinfecting injections, or, in fact, without any treatment whatever.

The notable features of the Ogmore cases were that: (*a*) the fatal cases (at Nantymoel) were attended by the midwife H. L.; (*b*) all the cases attended by the midwife A. W. recovered; and (*c*) during the interval between the first and second fatal cases H. L. attended several cases without the slightest ill effects. The midwife A. W. did not cease attending cases for even a day, and, whilst H. L. was abstaining, A. W. probably attended a case daily on an average. Two of her cases were severe puerperal fever and both of the patients recovered.

The above statements show that puerperal fever has prevailed to an abnormal extent in this district for some years—that it was endemic and never entirely absent from the locality. I was informed by some of the oldest practitioners in the Garw Valley that cases of [illegible] there at intervals for 13 years [illegible] fever, *indigenous in some of the* [illegible] outline of the sanitary conditio[illegible] the district, and I would only add that the two valleys are totally distinct and separated by high hills of Penant sandstone and that there is no intercourse between the midwives of the one and those of the other. Notwithstanding this fact the disease *has been prevalent in* both valleys.

It is well known that defective sewerage and typhoid fever go hand-in-hand. This is clearly exemplified by the fact that Pontycymmer (in the Garw Valley) and Tynewydd (in the Ogmore Valley), the most insanitary spots throughout the district, suffer the most from typhoid fever. I should also mention that these localities are the most densely populated. It is possible, if not probable, that there might exist a close relationship between puerperal fever and of insanitary atmosphere, containing sewer gases, arising from untrapped and badly ventilated drains or sewers or from the soil which is often damp and boggy and impregnated with excrement and decomposing vegetable matter. Of this I cannot speak [illegible] .eved by some to have intimate [illegible] puerperal fever. Scarlet fever has been prevalent in these valleys for years, but the accompanying tables do not conclusively show the connexion, if any, that [illegible] I have notes of [illegible] ippened in house[illegible] and the experienc[illegible] (which coincides with my own) may be summarised thus: 1, That the majority of cases confined in houses infected with scarlet fever escape entirely. 2 That occasionally the mother takes scarlet fever but does not develop any puerperal symptoms such as rigors, high temperature, abdominal tenderness, fœtid lochia, &c., and generally recovers.

The following are noticeable facts also: 1. That not a single case of diphtheria had been reported to the medical officer of health during the last five years. Indeed, I am [illegible] known *in these valleys.* 2. [illegible] to be attacked than multi[illegible] ich primiparæ suffered there [illegible] t of 14 where multiparæ suffered there were only 4 fatal cases. 3. That the fever more readily attacks, and is more fatal in, cases of easy and natural labours. 4. *That the above statistics and history* of cases do not afford conclusive evidence of the relationship, if any, between this disease and other zymotic diseases, such as erysipelas, measles, whooping-cough, and diarrhœa. 5. That a number of cases attended by infected midwives escaped entirely. 6. That the infection in this disease is most subtle, persistent, and portable, and more difficult to get rid of than in almost any other disease, or probably appears to be so, owing to the susceptibility of the puerperal woman to such an infection. 7. That all the fatal cases in one locality were attended by one and the same midwife. 8. That midwife P. attended six cases within a space of four months and that three of these (primiparæ) terminated fatally.

I [illegible] ntioned that *nearly* all the confinements [illegible] the county are attended by [illegible] as they are called, whose [illegible] eptics, and infection is *nil.* I have interviewed a few of the above midwives who frankly admitted that they were *ignorant that, they might have been* the means whereby the disease was spread, and that up to a recent date the necessary precautions against the spread of the disease were not observed for the simple fact that they were ignorant of the danger connected therewith. Such a condition of affairs is not unique—viz., that midwives spread puerperal fever broadcast and are not interfered with. Even

measures are carried out in a systematic manner, though however thorough it may be the personal equation in a very few cases must not be forgotten. Auto-infection plays a part in some cases and infection from without in others, and [illegible] traced in all cases there can [illegible] [illegible]st asepsis in all local procedures should be practised on the part of the practitioner and septic conditions should be treated by the application of antiseptic treatment. The final word on the question as to what is the most scientific way of dealing with the puerperal period has been spoken—asepsis and antisepsis; the other question as to how the infection arises in *all* cases may be left for future work.

THE CAUSATION, DIAGNOSIS, AND TREATMENT OF PERFORATING ULCER IN TYPHOID FEVER.[1]

By E. W. GOODALL, M.D. Lond.,

MEDICAL SUPERINTENDENT OF THE EASTERN HOSPITAL, HOMERTON.

THE increased frequency with which laparotomy is performed with the object of suturing a perforated intestinal ulcer in typhoid fever has rendered the differential diagnosis of abdominal complications in the course of that disease of far more importance than it was formerly. Moreover, in order that surgical treatment shall have the best chance it is imperative that a correct diagnosis shall be made as early as possible, a matter very often of extreme difficulty. I have thought that the records of a large fever hospital would furnish some facts of value bearing on the subject; hence I venture to bring it before your notice this evening. My observations are based upon the notes of 96 cases of perforation occurring amongst 1921 cases of typhoid fever under treatment at the Eastern Hospital, Homerton, during the 12 years 1892 to 1903. All these 96 cases were fatal with two exceptions, one in which an operation was performed and another where the nature and course of the symptoms justified a diagnosis of perforation, a case to which I shall refer again later. [illegible] will be found that perforation [illegible] [illegible]e cases and as there were 304 [illegible] was responsible for 31·5 per cent. or nearly one-third of the total. I think, however, that we may safely conclude that in quite a third of the total deaths perforation took place. The figures given above are not quite accurate inasmuch as a post-mortem examination was not made in every fatal case. There were 189 necropsies and in 68 (or 35·9 per cent.) perforation was found. In some of the cases perforation had hardly been even suspected during life.

Causes.—62 of the patients were males and 34 were females. I have no explanation to offer of the greater frequency of this complication in the male sex. It is seldom met with in children under ten years of age; I have notes of only eight such cases and, curiously enough, seven of them were girls. The youngest case was that of a girl aged six years. It seldom occurs in patients over 40 years of age—seven cases only—the oldest being a man aged 63 years. The ages from ten to 24 years furnish the largest number of cases (52). As perforation does not usually take place until the sloughs in the intestine have begun to separate it is seldom met with before the third week of the disease. In fact, in only five out of 82 cases in which accurate records are given of the length of the illness did perforation take place during the second week; the earliest day was the tenth. I have never known it to occur during the first week. Most of the cases occurred during the third, fourth, and fifth week (64 out of 82); in nine cases perforation occurred during the sixth, in three during the seventh, and in one during the tenth week; of these last 13 cases seven took place during relapses of the fever. Two of the fifth week cases were cases of relapse, so that 9·3 per cent. of the perforations happened during a relapse. So far as perforation is concerned relapses may be reckoned as first attacks, so that this complication is unusual during convalescence. Of an accurate note was recorded of the state of the ulcers, in 41 sloughs were still present.

With reference to the sort of case in which perforation most commonly occurs I am sure that severe cases furnish a large proportion of the total number; in 14 of the 96 cases perforation had taken place before admission, so that of those I know nothing as to the nature of the attack, but of the 82 remaining cases 39 were certainly very severe ones, while of the other 43 very few could have been called mild. And at necropsies on patients in whom perforation has occurred it is very unusual to find scanty ulceration. Amongst the 68 post-mortem examinations already referred to the mildest case from this point of view was that of a lad, aged 12 years, in whom only three ulcers were found. In the large majority of the cases the ulceration was both extensive and deep. I find, too, that in 20 of the 96 cases (20·8 per cent.) perforation was preceded by hæmorrhage which is another complication that is found most frequently in the more severe forms of the disease. The conclusions from these facts are that perforation occurs most frequently in severe cases and in the acute stage of typhoid fever.

The immediate or exciting causes of perforation that have been described are many: errors in diet; unsuitable purges, whether administered by the mouth or the rectum; straining at stool; sudden movements on the part of the patient, usually in delirium; careless movements of the patient by the nurse or attendant; and distension of the bowels. But while not denying that perforation may result from any one of these causes, more especially, so far as my own experience goes, sudden movements of the patient by himself or others, yet I do not believe that any of these are at all common. I will even go so far as to say that they are uncommon, at any rate in hospital practice. Even of the 14 cases in which perforation had taken place before the patient's admission to hospital in only one or two was there any reason to believe that the act of removing the patient had been the cause. In most of them perforation had occurred before removal. In my opinion by far the most common cause of perforation is the mere extension of the necrotic process to the peritoneal coat of the bowel. A bit of the peritoneum is included in the slough and as the slough has got to separate a hole must result sooner or later. Sometimes, when the peritoneum is involved in the inflammation that precedes necrosis, lymph is thrown out and seals the minute hole formed in the first instance but with the separation of the slough the hole becomes larger and the adhesions then give way. This is what both my clinical and post-mortem room experience has taught me. Though I have specially looked for it, I have never seen a slit-like perforation, suggesting that the peritoneum has been torn through. This condition has been described by the most competent observers but it must be very rare. I would not, however, on account of its rarity, have you think that I am for relaxing the order given to nurse and attendants that the patient suffering from typhoid fever is to be moved with the greatest possible care.

Symptoms and diagnosis.—By far the most constant symptom is pain in the abdomen; this pain is nearly always sudden and frequently severe. Still in at least 20 of the 96 cases the initial pain was slight. The seat of the pain is most often in the lower part of the abdomen, especially in the right iliac region. It is not at all uncommon, however, for the patient not to be able to localise the pain and to say that it is felt all over his abdomen. Not infrequently, also, the pain is referred to the epigastric region or even to the lower part of the chest. It may exceptionally be referred to almost any region of the abdomen. In two of the cases there was in addition to pains in the lower part of the abdomen pain at the end of the penis. One of the points that I think should be emphasised about the pain is the suddenness of its onset, even though it be slight. I doubt, however, whether one would be [illegible] merely from the occurrence [illegible] that it is important to a[illegible] other symptoms. These may be either local or constitutional. The former are of most importance: tenderness, sometimes exquisite, most often in the right iliac region; rigidity either in this same region or all over the abdomen; alteration in the condition of the abdomen in the direction of either distension or retraction, if this alteration has been observed to occur somewhat quickly after the pain. Obliteration of the liver dulness may be found quite early, but as a rule, if it does occur, occurs several hours after perforation.

---

[1] A paper read before the Hunterian Society on April 27th, 1904.

Of what I may call the constitutional symptoms one of the most important is shivering. In 25 of the cases (26·0 per cent.) shivering occurred about the time of perforation or within an hour or two of it. The shivering may be of all degrees up to a severe and prolonged rigor. While shivering usually occurs at the time of the pain or soon after I have known it to precede by some hours any other signs. Thus (Case 1) a girl, aged 12 years, had a rigor at 1 P.M. on Nov. 15th but presented no abdominal signs till 37 hours later and these were the signs of peritonitis which proved fatal a few hours later. Again (Case 2), a man, aged 31 years, suffering from a very severe attack, had a rigor one morning at 10 A.M. The pulse became quick and running, the respirations thoracic, and occasionally the patient lay with his legs drawn up, an unusual attitude in this disease apart from abdominal complications. At noon the patient, who was quite conscious, declared that he had no pain at all though the abdomen was slightly retracted and rigid. It moved on respiration. There was no abnormal dulness. At 11 P.M. he was seized with severe abdominal pain, became collapsed, and died in eight hours. Other initial symptoms, important but of less *frequency, are vomiting, collapse, a change of colour in the* face (the patient becoming of a slightly grey or cyanotic hue), an anxious expression (not usual in children), the passage of two or three loose stools where previously there has been constipation or an infrequent action of the bowels, and an increase of pulse-rate. A marked fall of temperature is the exception. My belief is that a fall of temperature usually means collapse or the onset of peritonitis. At any rate, it is not often met with immediately following perforation, though it is not uncommon to find it a day or two later.

I would emphasise the statement that the sole occurrence of any one of the symptoms which I have been enumerating should always be the signal for most careful examination and observation of the patient with a view to the detection of peritonitis. When one simply enumerates a number of symptoms as indicative of any particular disorder or complication it often seems to the reader or listener that diagnosis should be, if it is not, easy. But it is very difficult, if not impossible, to convey in words the varying degrees of severity or prominence of symptoms, together with the combinations and sequences of them, all of which points are, perhaps at times unconsciously, taken into account by the experienced observer. It is a trite saying that it is easy to be wise after the event. I will relate, however, one or two cases in which I went wrong, more especially as they will serve to illustrate points about which not much is said in the ordinary text-books.

CASE 3.—A man, aged 56 years, was admitted to hospital on Dec. 15th, on the fourteenth day of his illness. He was suffering from a definite but mild attack of typhoid fever. There was nothing special about his case till two days after admission, the sixteenth day of his illness, when I was called to see him at 8.45 P.M. "Soon after 8 P.M he had a rigor, which lasted about ten minutes; his temperature was then 101° F. Now the patient is still shivering a little. He says that soon after 7 P.M. he passed a stool and then had a little abdominal pain, which he still has. It is not at all severe and is referred to the left side of the abdomen below the level of the umbilicus. The abdomen is a trifle full and the muscles on both sides a little rigid; liver dulness normal; no absolute dulness anywhere over the abdomen, but some impaired resonance in a band just below the umbilicus, stretching from about the middle of the right iliac fossa slightly upwards towards the upper part of the left iliac fossa. The percussion note, however, varies in different parts of the abdomen. The bowels were opened freely just before the rigor and again just after it. The motion was loose and somewhat pasty. Patient also vomited just after the rigor, bringing up some milk tinged with bile; pulse 102, small, not wiry, regular. No sign of collapse." Midnight: "For the last hour or so patient has had no pain; he is now sleeping quietly and the pulse is quiet. He has passed another stool with curds and probably a little slough in it. Patient woke while I was present. The rigidity of the abdominal muscles has gone off; he says he has some abdominal tenderness when he moves, mostly on the right side." Nourishment by the mouth was omitted, except a little water or ice. The next day, the seventeenth of the illness, I noted that the patient slept well during the night. There was still some tenderness round the umbilicus for about four inches. There was no more shivering or vomiting and the pulse was good (88). There was now no abdominal dulness, but the same note was present all over. Nourishment by the mouth was resumed (whey). At 6 P.M. the note was as follows: "Up to about 4 P.M. the patient had occasional pain; since that at intervals of about 10 to 15 minutes he has had rather sharp attacks of pain. He has been retching about four times. Now he has no pain, but there is some tenderness on pressure over the abdomen. He says that the pain, when he has it, is all over the abdomen and not in any particular region. The abdomen is a little fuller than it was this morning, and a little tense, equally on both sides. The percussion note is not the same all over, being a little flatter in the lower half. The liver dulness is present but confined to a strip about one and a half inches wide at the costal margin. It was more than this before. P. 96, rather smaller than before. The pulse seems to me to be too good for peritonitis or perforation. No more shivering. Not restless. The retching has been violent." At 12.30 A.M. (six hours later) the abdomen had become more tense, there was occasional slight retching, the pulse was smaller, there was hardly any pain, but slight tenderness. There was no bell-sound over the abdomen. At 9.45 A.M. the patient was much worse, the pulse was feebler, and the face was clammy. He had had pain during the night but not at all severely till about an hour ago; there was frequent vomiting; the abdomen was more distended; there was no liver dulness. He was much relieved by morphine, so that he had no more pain and no more vomiting after 2 P.M. The patient gradually sank and died at 6.50 P.M., about 48 hours after the first symptom. He was quite conscious up to the end and, in fact, during the afternoon he gave certain directions as to the disposition of his affairs.

A post-mortem examination revealed a perforation and peritonitis. The perforation was nine inches above the valve and was a large one, half an inch by a quarter of an inch. The last 18 inches of the small intestine were ulcerated. The great omentum was found covering the whole of the small intestines, reaching down to the brim of the pelvis. On the left side it was very firmly adherent to the pelvis by fibrous bands which I had to cut through. Evidently there had been peritonitis at some previous time. The omentum itself was very thick, fat, and fibrous.

The following note was made after the post-mortem examination on Dec. 20th: "This case has been most instructive. When I saw the patient not long after the rigor on the evening of the 17th I of course at once thought of perforation. The dulness I noted then I think was very likely due to the thickened omentum found post mortem. What put me off absolutely diagnosing perforation was the excellent general condition of the patient. I did not indeed put him on the visiting list[3] till I saw him at midnight, ordering the letter to go by the first post in the morning. I only put him on the 'visiting list' then as a matter of precaution, because he was better than earlier in the evening. Next morning he was still better *to such an extent that* I quite negatived the idea of perforation and resumed the nourishment by the mouth."

Had the patient not been 56 years of age (and looking somewhat older) I should, I think, have urged an exploratory operation on the night of the 17th. But his age, combined with the fact that the symptoms were slight, caused me to negative the idea. The post-mortem examination showed that it would have been, on the whole, a favourable case for operation, though the ulcer that had perforated was rather large.

CASE 4.—A youth, aged 17 years, was admitted to hospital on the twenty-first day of his illness which was severe. No unusual symptoms were observed, except that at times the patient got a little cyanotic, till the twenty-fifth day when at 10.45 A.M. he complained of pains in the abdomen and at 11.15 he began to shiver a little. I saw him at 11.30 A.M. He was still shivering a little. His pulse was 118 and the respirations were 20; previously they had averaged 98 and 28. The patient was a little dusky. The abdomen was slightly retracted and the patient said that he had pain all over it. There was very slight rigidity of the lower half of the abdomen below the umbilicus on both sides and liver dulness was present. The bowels were moved at 11.15 and at

---

[3] Patients are not put on the "visiting list" unless they are considered to be dangerously ill.

11.45. I was doubtful about perforation. At 1.45 P.M. I noted that the shivering had stopped at noon. The patient was much more comfortable. The bowels had been opened once and urine passed since 11.45; the pulse was soft; there was no abdominal pain and the abdomen was not at all rigid, and the colour was better. I thought that after all perforation had not occurred. The patient had a slight attack of pain at 4.15 P.M. and again at 6 P.M. At 9.30 P.M. he was worse; since 8 P.M. he had retched two or three times, the pulse was small, compressible, and weaker and he looked worse; the abdomen was mode- [illegible] ver dulness was quite [illegible] he abdomen even on [illegible] There could now be no doubt that perforation had occurred and laparotomy was performed at 11 P.M. There were gas and fluid in the peritoneal cavity with much peritonitis. The perforation was about two inches above the valve and was closed with sutures. The patient gradually sank and died 41 hours after the operation. A post-mortem examination showed that the last foot of the small intestine was most severely ulcerated.

CASE 5.—A boy, aged 13 years, was admitted to hospital on the tenth day of a not very severe illness. On the fourteenth day, at 4 P.M., he had sudden pain in the abdomen; it was not severe enough to make him cry out but he began to make a fretful noise. The patient, I may add, had been fretful since admission and was always, as the nurses' expression is, "very sorry for himself." The pain was relieved by hot fomentations but came on again at 4.30. I did not see him till 6.40 P.M.; he then complained of pain in his abdomen and on being asked whereabouts it was he moved his hand all over his abdomen. The abdomen was a little retracted and the lower half of each rectus was distinctly rigid; liver [illegible] at 6.45 it had been [illegible] and ice was applied [illegible] 108. At 11.45 it was also 108, of good volume, and the pain was easier; the other symptoms were about the same. After 11 P.M. the boy had a good night and slept well. The next morning the abdomen was flat and not so retracted as on the previous day; it was still painful all over and rigid in the lower half. The pulse was 124 and fairly good. There was great pain during micturition; there was no vomiting or retching. The boy looked better. When he was left alone and watched from a distance he appeared to be fairly comfortable and lost the distressed look he had when anyone was by his bedside. When this note was made he was amusing [illegible] newspaper. At 3 P.M. on the same [illegible] e with severe abdominal pain and [illegible] owed the usual signs of peritonitis [illegible] seventeenth day.

At the post-mortem examination a minute perforation was found eight inches above the valve. There was most intense general peritonitis. The ulceration of the small intestine was not severe. In each of these three cases a distinct remission of the symptoms occurred which quite deceived me and led me to suppose that after all such a serious event as perforation had not taken place. If the chief symptoms indicative of perforation were not met with in other conditions in typhoid fever the diagnosis would be very much simplified. But sudden (and even severe) abdominal pain, shivering, and rigidity of abdominal muscles may all occur and yet as far as one can be sure no perforation have taken place. For instance (Case 6), a man, aged 32 years, suffering from a rather severe attack of typhoid fever, was seized one morning with marked shivering and abdominal pain. There was, at the time no local symptom besides the pain. Shortly afterwards the patient vomited. In the evening the abdomen had become somewhat distended and there was pain in each iliac fossa. The patient was retching and had hiccough. His pulse gradually failed and he died 14½ hours after the onset of the symptoms. The post-mortem examination revealed severe ulceration of the ileum. Several of the ulcers were large and their bases were very thin. On the peritoneal aspect were patches of lymph and there was a little lymph on the under surface of the great omentum. There was some dark serous fluid in the pelvis. There was no general peri- [illegible] h was made no perforation [illegible] be found.

[illegible] s, was admitted to hospital [illegible] een suffering from severe abdominal pain and diarrhœa for four days before admission. On admission he was found to be somewhat collapsed, was perspiring freely, but had a fair pulse. The abdomen was full and tympanitic, it was tender on palpation, and there was pain in the right iliac region. Breathing was thoracic. His temperature was 100·2° F. and the pulse was 96. Laparotomy was performed five hours after admission but absolutely nothing wrong could be found in the abdominal cavity. The abdominal pain p[illegible] tinued to progress fairly well. [illegible] signs of right basal pneumor [illegible] quickly became worse and died the same evening.

Permission was given to examine the abdomen only, but except for the intestinal ulcers nothing wrong was found. It was a question in this case whether the abdominal pain may not have been the referred pain of pleurisy.

CASE 8.—A man, aged 33 years, was admitted to hospital on the fourteenth day of his illness. It was noted on admission that the abdomen was hard and resistant. I was requested to see him the next day because it was a question whether perforation had taken place. At 11 A.M. he had had an attack of abdominal pain which increased during the next two hours. At 1 P.M. the abdomen was full and resonant all over. It was rigid on firm palpation; the liver dulness was obscured. There did not seem to me to be quite sufficient evidence to justify an operation. Hot applications to the abdomen gave much relief and next day all the pain had gone. On the twentieth day of his illness (five days after the attack of pain) there were well-marked signs of pleurisy with effusion on the right side. Possibly this (as in the case related above) was enough to give rise to the abdominal symptoms. At any rate, when five days later I performed a laparotomy on account of unequivocal symptoms of perforation I could find no evidence of any previous abdominal lesion. The patient recovered.

I could give notes of other cases in which, though perforation [illegible] during life, [illegible] with these [illegible] peritonitis [illegible] two in which there were abdominal symptoms suggestive, though by no means conclusive, of perforation or peritonitis, but in which the patient recovered and the diagnosis was never cleared up.

CASE 9.—A woman, aged 28 years, was admitted to hospital on Dec. 3rd with typhoid fever. She had been ill for rather more than a fortnight and five days before admission she had miscarried. She had a sharp attack but did very well and was beginning to convalesce (her temperature having shown signs of settling down to normal for upwards of a week) when on Dec. 27th at 4.30 A.M. she was during sleep seized with very severe abdominal pain and vomiting. The medical officer was summoned; the patient had pain, tenderness, and slight rigidity in the right iliac fossa. The pulse was 140, small, and somewhat wiry, and the temperature was 98° F. It was thought that something serious had happened and her friends were sent for. But in the course of three hours or so the urgent symptoms had all gone and by the evening the patient was as well as she had been before.

CASE 10.—A woman, aged 28 years, was admitted to hospital on Dec. 19th, having been ill since the 4th. She went through a severe attack of typhoid fever and her temperature did not settle down to normal till Jan. 16th. Ten days later, [illegible] on of the liv [illegible] was at firs [illegible] vere. There [illegible] wing night the temperature rose to over 100° F. The pain became worse. There was bilious vomiting on seven occasions between 1 P.M. and 1 A.M. The patient preferred to lie on the right side. Her face wore an anxious expression. Her pulse was small and running; the rate was 168 at noon and remained high during the day, being 152 in the evening, when the temperature was nearly 103°. The abdomen was not distended; there was exquisite tenderness over the region of the gall-bladder, where there was some fulness. The abdominal wall was held rigidly, the rigidity being most marked on the right side. There was just a faint yellowness of the sclerotics. There was impaired resonance or percussion over the whole of the right half of the abdomen to about two inches above Poupart's ligament. There was no vomiting between 1 A.M. and 2.30 P.M. A simple enema was administered which produced a fairly copious, brown, formed stool. No stones were to be found there was right basal pneumonia but no peritonitis. There were several healing typhoid ulcers in the intestines.

The case in which a suppurating mesenteric gland had given way and caused death by setting up peritonitis (Case 18) was that of a woman, aged 42 years, who died on the twenty-third day of her illness. The symptoms were those of peritonitis only.

Of the three cases in which the perforation was situated in the large intestine in one instance it was in the ascending colon, in a second in the descending colon, and in the third in the sigmoid flexure. The latter two were diagnosed as perforation cases; there was pain which was most marked in the left side of the abdomen. The first case of the three (Case 19), however, was not diagnosed as regards the perforation. The special symptoms connected with this were pain and œdema in the right flank for four days before death and occasional vomiting. Post mortem there was an abscess behind the cæcum; there was no general peritonitis. These three cases were all very severe ones.

The three appendix cases were all interesting and difficult. In one (Case 20), a girl, aged eight years, a sudden attack of abdominal pain had occurred on the twentieth day. She said that the pain was all over the abdomen. The abdomen was sunken and soft and there were absolutely no localising signs but the patient was suffering from a very severe attack of typhoid fever and was at times delirious. There was no more pain till the twenty-eighth day. On the thirtieth day I made a careful examination; the abdomen was moderately distended but quite supple. The patient cried and moaned when the abdomen [illegible] was painful; but there was no sign [illegible] or even peritonitis. She died on the [illegible] It was found that the appendix was bound down to the brim of the pelvis by soft adhesions; in it were two perforations. There were about four ounces of creamy pus in Douglas's pouch but there was no general peritonitis.

In the second case (Case 21), that of a woman, aged 23 years, there was indefinite pain in the abdomen on and off for 18 days before death, with occasional vomiting. The day before death there was some rigidity of the abdomen. Perforation was not diagnosed. Post mortem there was general septic peritonitis due to a perforation of the appendix.

In the third case (Case 22), that of a boy, aged nine years, the patient had a mild attack followed by a relapse on the twenty-third day. On the twenty-fifth day a small nodular swelling was observed in the abdominal cavity to the left of the umbilicus. The abdomen was full and tympanitic. On the twenty-seventh day there was bilious vomiting, which continued occasionally till the patient's death on the twenty-ninth day. There was some slight abdominal pain about this time but it did not last long. Beyond slight abdominal distension and the indefinite mass already mentioned which could still be felt on the twenty-seventh day, there were no abdominal signs and perforation was not diagnosed. Post mortem there were general septic peritonitis and a perforation close to the tip of the appendix.

I have looked through the notes of the 59 cases in which the small intestine was perforated and in which a necropsy was made in order to find out whether there were any signs to indicate the distance of the perforation from the ileo-cæcal valve, but I do not find that there were. It is true that in one case,[5] that of a woman, aged 39 years, who died within ten minutes of the bowel having given way, the perforation was found a little higher up than usual—two and a half feet—but I think that was merely a coincidence, for in other cases in which the perforation has taken place as high or even higher the symptoms were no more acute or severe and the fatal termination did not occur sooner than in those cases in which the perforation was situated close to the valve.

I have spent a considerable time on the question of diagnosis because that is the most important one. If perforation is diagnosed there is only one course to be followed—viz., laparotomy, with usually suture of the perforated portion of bowel. After reading through the reports of a number of a cases that have been operated upon, recorded in various journals and periodicals, I quite agree with Finney[6] in his conclusion that a moribund state of the patient is the only contra-indication to operation; it is certainly astonishing what patients who are desperately ill with typhoid fever will stand. I suppose everyone will agree with me in saying that if the patient is left he is almost certain to die. I am aware of the fact that cases are on record in which patients have recovered after having presented all the symptoms of perforation and peritonitis, and I believe that some of these cases really have perforated. An extremely interesting case of the kind is reported by Hare in his work on the "Cold Bath Treatment of Typhoid Fever" (p. 182). In this instance the patient died from some other complication six weeks after the occurrence of perforation and the post-mortem appearances quite bore out the diagnosis. For the full details I must refer you to Hare's account of the case. In my own practice I have had one such case (Case 23). A young woman, 20 years of age, was seized on the nineteenth day of a severe attack of typhoid fever with severe abdominal pain. The pain continued. On the twenty-first day the abdomen was rigid and painful, especially in the right iliac region. Respiration was laboured, there was vomiting, and the expression of the countenance was anxious. On the twenty-second day at 8 A.M. the patient, having had pain and retching during the night, became pulseless and cyanosed but revived with champagne. On the twenty-third day the abdomen became distended and tympanitic and there was dulness in the right iliac fossa. Next day there were also marked tenderness and some swelling of this region. On the twenty-fifth day it was noted that the abdomen was very tense and the skin pitted on pressure and on the twenty-sixth day there was a [illegible] pointing to some peritonitis (probably [illegible] d on and off for nearly three weeks longer, the only new symptom being marked peristalsis which was noticed on the thirty-second day. The patient ultimately made a good recovery. I may add that in this case an operation was [illegible] i. Such cases, however, are very exceptic [illegible] ie I have related to the 68 in which the fact of perforation was ascertained by a post-mortem examination a recovery rate of 1·4 per cent. is obtained. Now, this is very much lower than that of cases operated upon, even when all allowances are made for selection of cases. The recovery rate in 362 cases collected by Harte and Ashhurst[7] was 26 per cent. They tabulated all the cases they could find recorded from Mickulicz's first case in April, 1884, to about the middle of 1903. Hawkins estimates the recovery rate after operation as about 25 per cent.[8] I cannot help thinking—nay, I am pretty sure—that this rate is considerably higher than is actually the case. Whereas I believe that very nearly every successful case gets reported I am sure—for I know of some—that every unsuccessful case does not. Of 49 consecutive cases occurring in the Asylums Board's hospitals, 36 of which have been reported in the Board's annual reports, four recovered, a recovery rate of 8 per cent., which is much higher than that of patients left to themselves but very much lower than that of the cases collected by Harte and Ashhurst.

I do not think that it is necessary for me to do more than mention the most essential points about the operation. They are: 1. Early operation, which means early diagnosis. I would not now hesitate to open the abdomen if there had been sudden though not necessarily severe pain, with localised tenderness and rigidity, more especially if there had been also shivering. I know that occasionally a perforation will not be found, sometimes not even peritonitis will be found. But the results of published cases of this kind are very favourable. Of 26 such cases collected by Harte and Ashhurst in the paper already quoted—cases in which no peritoneal lesions were found—16 recovered. It has been suggested that the abdomen should be explored in what has been termed the pre-perforation stage. But I do not believe it is possible to diagnose this condition and I do not recommend an operation in cases where there are only such vague symptoms as pain and distension. I am quite sure from what I have seen at operations for perforating typhoid ulcers that peritonitis may precede the perforation. Very often, however, the signs of preceding peritonitis are not at all obvious and one is astonished to find at an operation performed within two or three hours of the symptoms of perforation most severe and extensive peritonitis at the existence of which one had not even guessed. Of course, if there is profound collapse following immediately upon the admit of it. But my experience is that serious collapse immediately after perforation is the exception rather than the rule. 2. Rapid performance of the operation is of course very advisable. And one thing necessary to insure this is that the perforation should be found as soon as possible. In most of the cases the perforation takes place within 24 inches of the ileo-cæcal valve. In 55 cases in which the exact site of the perforation was noted post mortem in 32 it was within 12 inches of the valve, in 15 in from 12 to 24 inches, in five in from 24 to 36 inches (in one of these it occurred in Meckel's diverticulum; the only sign was tenderness on pressure on the abdomen and perforation was not diagnosed during life), in two in from four to five feet, and in one over five feet. Therefore it is hardly necessary to say that if the perforation is not found at once on opening the abdomen the ileo-cæcal valve should be taken up and the small intestine examined upwards from it. If no perforation is detected in the small intestine the appendix and large intestine should then in their turn be scrutinised.

[7] Annals of Surgery, January, 1904.

[8] The Practitioner, January, 1904.

As in most cases the perforation is found in the right lower quarter of the abdomen I think that the best incision is one in the right linea semilunaris or thereabouts. But I think that if I had to deal with a case where the local symptoms were most marked in some other region I should make my incision accordingly. In most instances it will be sufficient to suture the perforated intestine with a Lembert's suture or one of a similar nature. But if it be found impossible to do this on account of the large size of the ulcer or the thickness or induration of its edge I think that probably the best course to pursue is to fix it in the abdominal wound, making an artificial anus which one would hope to deal with later. Other methods of treatment (such as resection of the affected portion of gut) require more time and skill and are therefore to be undertaken only in special circumstances. As to whether irrigation and drainage should be employed depends on the nature of the case. They should certainly be carried out if septic peritonitis is found.

I need hardly go into other details of the treatment here. I will only mention that, unless the patient is suffering very severe pain before the diagnosis is made and laparotomy definitely determined upon or rejected, it is not wise to dose the patient with narcotics which will only mask important symptoms. I believe this occurred in one of the cases of perforation of the gall-bladder mentioned above. As regards the anæsthetic for the operation I have used a local anæsthetic in one case only (eucaine); that was not a success and a general anæsthetic had to be resorted to after all.

ON THE BENEFICIAL EFFECTS OF SODIUM ARSENIATE EMPLOYED HYPODERMICALLY IN TSETSE-FLY DISEASE IN CATTLE.

By EDWARD J. MOORE, F.R.C.S., L.R.C.P. IREL.,
DISTRICT MEDICAL OFFICER, ASABA, SOUTHERN NIGERIA, WEST AFRICA.

SOME months ago the Government of Southern Nigeria established an experimental farm with the intention of teaching natives to use cow's milk as an article of diet for their children and thereby to put a natural check on twin murder by removing the reason on which this practice is based—viz., the inability of most ill-fed native women to rear two children. The site was selected as being one of the few localities where horses and mules thrived fairly well and 22 cattle, principally West Indian, were established there. These remained in health for a month and gave large quantities of milk, then the flow practically ceased and the animals became rapidly emaciated. The symptom which at first directed attention to the condition of the animals was an unwillingness to eat and on examination the teeth were found to be loosened; it was also noticed that there was a running of water from the eyes. The limbs below the knee and hock were the seat of a puffy swelling which did was con[illegible] in the form of a hard, elastic, [illegible] bove the hoofs in front and a m[illegible] corresponding locality behind. In most cases there was a noticeable difficulty in passing urine, the animals "hunching" themselves up and straining very much during the act and the flow instead of being continuous was intermittent, which suggested loss of contractility of the bladder.

The affected animals rapidly lost flesh; the lymphatic glands, especially those in the groin, the axilla, and the root of the neck, became very much enlarged; there was moderate fever, intermittent in character, and never exceeding an elevation of 3° F.; the respirations were markedly increased in number and in the early stages there was a dry, hacking cough. After the lapse of a month drowsiness supervened, deepening into profound slumber which lasted 36 hours and terminated in death. Most of the animals died before the onset of the sleepy stage from obstinate constipation and retention of urine, due probably to paralysis of the intestines and bladder.

Dr. Chichester, who first examined the animals' blood, found the trypanosoma present, and Mr. Young, the superintendent, has drawn my attention to a peculiar spirillum-shaped organism with very active motion present in large numbers in the blood of one of the animals. This I am at present investigating.

Fowler's solution of arsenic was administered in one-drachm doses three times daily without giving rise to any material improvement. Later single doses of one ounce daily were given. These had to be discontinued as they increased the already existing tenderness of the mouth to such an extent that the animals refused all food and their general symptoms became aggravated.

In these circumstances I prepared a 1 per cent. solution of sodium arseniate, rendered slightly alkaline with sodium bicarbonate, and selecting the worst case where drowsiness had supervened and the condition appeared to be hopeless I injected one ounce of the solution subcutaneously on two occasions at an interval of a week. The beneficial effect was marke[illegible] firm, the appetite reappe[illegible] as hardly apparent on ins[illegible] apidly, and the quantity of milk, which had fallen to three-quarters of a pint, increased in a month to seven pints. The injections were tried with similar good results on all the surviving cattle.

The supply of arseniate solution having run out the injections were discontinued, with the result that the cattle maintained their improvement for a month and then slowly relapsed. Fowler's solution was then injected in one-ounce doses but it caused such extensive sloughing that it had to be discontinued. The arseniate solution is now being tried in two-ounce doses of 1 per cent. solution injected fortnightly with promising results.

There is no doubt from these experiments that single large injections of sodium arseniate, ten grains or even more, well diluted and given at intervals of a fortnight, exercise the most marked beneficial results in cases of advanced tsetse-fly disease in cattle, and I believe that in this procedure, combined with the prevention of reinfection, will be found the most satisfactory treatment of the condition. I would also suggest its employment in the human subject, in whom single injections of 20 minims do not seem to produce unpleasant effects.

THE DOWNES ELECTRO-THERMIC ANGIOTRIBE.[1]

BY H. MACNAUGHTON JONES, M.D. Q.U.I., M.A.O. R.U.I. (HON. CAUSA), F.R.C.S. IREL. & EDIN.

I SHOW these appliances for Dr. Andrew Downes of Philadelphia and you will agree with me that they are as skilfully devised and as beautifully constructed instruments as one can well conceive. It will be remembered that so far back as 1862 Baker Brown used the cautery in the

---

A 2

[illegible] Keith also adopted this method and so did Lawson Tait. Byrne adopted the galvano-cautery with considerable success for operations on the uterus, especially in malignant conditions. To Skene of Brooklyn, however, is due the credit of introducing the practice of electro-hæmostasis—that is, the control of hæmorrhage by the combination of forcipressure with heat produced by electricity.[2] Jacobs of Brussels in 1899 advocated it instead of ligature, clamp, or forcipressure by lever, the advantages claimed being that there is no sloughing of the tissues, that it enables us to act on a large surface, occluding the lymphatics and opposing an obstacle to the spread of infection. Also, no bleeding surface is exposed which is calculated to form adhesions with surrounding structures. Again, where tissues are friable and the application of a ligature is risky the application of hæmostasis is safe. Jacobs used various hæmostatic clamp forceps and indicated their use in cases of ovarian cystoma and pan-hysterectomy, as well as in appendicectomy and resection of the omentum.[3] He had then (August, 1899) performed six abdominal hysterectomies and two ovariotomies, besides other operations, without an accident and Skene had carried out over 200 cœliotomies without any hæmorrhage. The strength of the current was regulated by the interposition of a galvanometer, the time necessary for the desiccation being from half a minute to two minutes.

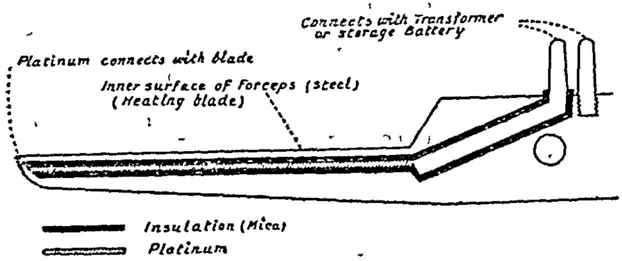
FIG. 1.

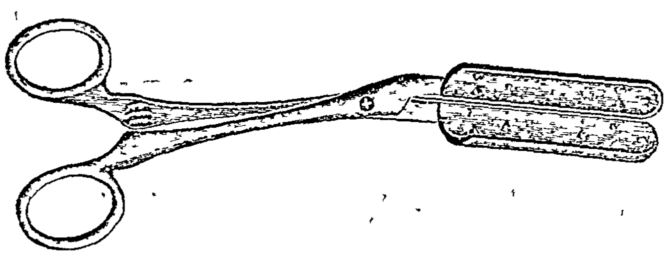


Connects with Transformer or Storage Battery
Platinum connects with blade
Inner surface of Forceps (steel) (Heating blade)
Insulation (Mica)
Platinum

Section of the heating blade.

The [illegible] aimed at by Dr. Downes were t[illegible] the heating point to 212° F., the insuring of cool shafts and handles to the instrument, greater security in the construction of the blades for the resistance of heat, and increase in the degree of pressure exerted.[4] The outfit consists of three angiotribes with blades of different widths, a quarter, three-eighths, and half an inch, one of the angiotribes being curved; a shield to protect the surrounding parts, a cautery knife, cable, transformer for use with the continuous or the alternating current, and the necessary electric supply. A maximum current of 60 ampères is necessary and the platinum in all the instruments should be of the same weight. The advantage of this high ampèrage is that the heat developed in the platinum causes the blades to heat more rapidly and effectually than with the lesser current, while there is less risk of burning out the platinum. The cable used is composed of mineral and rubber and will stand indefinite boiling, while it can be made in two portions so that the coupler alone need be sterilised for each operation.

FIG. 2.



Protecting shield.

Fig. 1 shows the section of the heating blade, the inner surface being made of steel, inside which are the layers of mica insulating the platinum. It also shows the connects with the transformer of a storage battery. Fig. 2 illustrates the protecting shield. Fig. 3A shows the lever angiotribe closed and Fig. 3B the same with curved blades. On releasing the lever the handles spring open. On reclosure when the lever is adjusted greater pressure is exerted on the blades. Fig. 3C shows the angiotribe without the lever. It is less powerful in its forcipressure action than that with the lever. Fig. 4 shows the cable and coupler. Dr. Downes has devised a foot breaker for the control of the current, so that it may be turned on when required by pressure of the foot. All that is necessary to heat the instruments is gradually to turn on the rheostat of the transformer until the platinum in the cautery knife (Fig. 5) or in the heater is a bright red. The transformer may be set at this point in the operating room, thus securing the necessary electrical supply by pressure of the foot at the required time. Water placed on the pressing surface of the blades will boil in 10, 15, or 20 seconds, according to the width of the blades already mentioned. From 10 to 30 seconds longer must be allowed after the application of the instrument for the hæmostasis.

In the latest reprint of his pamphlet on the subject Dr. Downes enters into details of the various operations—such as ovariotomy, salpingo-oöphorectomy, herniotomy, appendicectomy, and various intestinal operations, as well as those on the stomach—which may be performed by this method. He also describes the particulars of operations of hysterectomy, abdominal and vaginal. He has collected the particulars of 80 hysterectomies, 200 salpingo-oöphorectomies, one nephrectomy, 200 appendicectomies, and 20 ovariotomies for ovarian cysts, 16 of the hysterectomies being for cancer. Amongst those who have specially written on this method of hæmostasis are Hirst and Charles Noble of Philadelphia, Bovée of Washington, and Goldspohn and Murphy of Chicago.

ON DIABETIC NEURITIS.

BY F. W. PAVY, M.D. LOND., LL.D. GLASG., F.R.S.,

CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

IT is only of comparatively recent date that neuritis has been known to constitute a concomitant of diabetes. In making this statement it is not suggested that any new pathological state has presented itself. There are no grounds for thinking that the nerves escaped being affected by the abnormality existing in diabetes any more in former times than they do at present. What has happened is that knowledge has deepened and that attention is now given to symptoms that formerly failed to attract any special notice. Observation brings to our cognisance details that may have been previously allowed to pass unheeded before us, but once the mind has become centred upon them they are no longer likely to fail to receive the attention they merit.

Through circumstances of this nature I was led close upon 20 years ago to comment in the following manner upon symptoms of disordered nerve action that had forced themselves upon my attention in the course of my experience in connexion with diabetes [illegible] cussion on the Clinical [illegible] of the British Medical [illegible] one of the points I submitted for consideration was a set of symptoms of disordered nerve action that I had recognised as frequently to be met with in association with the disease. After alluding to them as connected with ataxia I proceeded:—

> A patient, a lady aged 48, whom I saw for the first time in 1871 and who had then been diabetic for ten years presented no symptoms of [illegible] 1880. She then began to complain of [illegible] f that year she was decidedly ataxic [illegible] patients of their condition is that [illegible] legs, that their feet are numb, that [illegible] nt expressed it, "as if he had [illegible] feeling as if his boots were a [illegible] ing or "lightning" pains are [illegible] æsthesia, so that a mere [illegible] pain; or it may be the [illegible] seam of the dress against [illegible] Not unfrequently there [illegible] escribes it, in the marrow of the b[illegible] that the [illegible] usual lo[illegible] pains a[illegible] ataxia [illegible] as happ[illegible] several [illegible] Indeed, than might have [illegible] put down by the local practitioner to [illegible] for [illegible]

Such is the narrative I gave in 1885 of the symptoms of disordered nerve action that I had noticed sufficiently often in connexion with diabetes to lead me to consider that they in some way or other constituted concomitant phenomena of the disease. It was in 1881 that my mind became possessed of the idea of giving fixed attention to the matter and I soon became struck with surprise at the frequency with which, when looked for, symptoms in one form or another of the condition in question were met with.

The description given, which as far as I am aware was the first to deal in a comprehensive manner with the variety of symptoms noticed to occur, affords a representation that meets our knowledge of the present day. Bouchard[2] about a year prior to the date of my communication drew attention to the loss of the tendon reflexes that may occur in association with diabetes, but his remarks only touched upon this particular point and were mainly directed to enlarging on [illegible] prognostic [illegible] is included in my sketch of nerve abnormalities depicted above. In their entirety the symptoms enumerated coincide with those met with in locomotor ataxia and at the time I wrote I viewed them as the result of lesion in the spinal cord. Our knowledge regarding peripheral neuritis was then in a developing stage and phenomena that are now known to be due to neuritis had previously been put down to lesion of the cord. The various symptoms of disordered nerve action associated with alcoholism were formerly attributed to disease of the spinal cord. These were the first to be shown to have been classified wrongly and to be in reality the result of lesion in the nerves. The train of symptoms associated with diabetes subsequently followed and became recognised as arising from nerve lesion. In turn the transfer has been made for the symptoms produced by certain mineral toxic agents, as, for instance, lead, arsenic, &c., and by the toxins of diphtheria and certain other diseases. Originally regarded as referable to disease of the spinal cord, they are now recognised as due to a morbid change occurring within the substance of the nerves.

Neuritis without dissent now occupies an established position as a source in some cases of symptoms so allied to those resulting from spinal disease as to have led former pathologists to regard them in such light. There is evidence to show that the change of view had been for a long time working forward but it was especially in the decade of 1880-90 that the consummation may be looked upon as having taken place. The histological change occurring in the nerve has been more studied in the alcoholic and some other

---

[1] THE LANCET, Dec. 12th, 1885, p. 1098

[2] Progrès Médical, 1884, p. 819

varieties of neuritis than in that of diabetes, but the evidence that has been obtained in connexion with the latter, in the instances where the opportunity of examination has occurred, accords with that pertaining to the former. A subdued form of inflammation may be looked upon as standing at the bottom of the pathological change and the lesion noticeable consists of advancing degeneration, ending in necrosis of the proper nerve texture. In this way the functional capacity of the nerve becomes interfered with and an intelligible explanation is given of the symptoms observed. In proportion to the loss of proper structural integrity, so is it to be expected that loss of functional power should occur and observation shows that these phenomena in reality run together.

Seeing that the effect of the lesion under consideration is more or less impairment of functional power of the nerve fibrils affected the symptoms that follow will depend jointly upon the particular fibrils involved and the extent to which the morbid change in them has advanced. We have to look then for the occurrence of motor and sensory disturbances, and as the nerves, in addition to their motor and sensory filaments, contain filaments connected with the sympathetic system, vaso-motor and nutritional disturbances are likewise found to occur. Symptoms of an exceedingly varied nature thus present themselves in cases of diabetic and, of course, also in other forms of peripheral neuritis, but they fall into the natural groupings to which I will proceed to give attention, taking them in the order of motor, sensory, reflex, vaso-motor, and nutritional.

Cramp is a motor phenomenon but it occurs as a symptom belonging to diabetes without signs of the existence of neuritis. It is especially noticeable in connexion with the early stage of cases in which the amount of sugar in the urine stands high and I consider it may be regarded as attributable to the direct effect of the sugar that is passing through the system upon the muscle, looking at the speediness with which the condition disappears under the reduction or removal of the sugar from the urine by the appropriate measures of treatment.

The motor derangement produced by peripheral neuritis accords with that of locomotor ataxia. It consists, therefore, of a want of proper coördinating power over the muscles instead of ordinary paralysis. Patients are sometimes in a distressed state of mind at the difficulty they experience in walking and fear they are going to lose the use of their legs. They think their condition arises from loss of muscular power due to paralysis, but they may be easily convinced otherwise by desiring them when seated to straighten out the leg and permitting them to see the power they possess of resisting attempts to bend it. With complicated movements as in walking a properly balanced play of individual muscles is called into requisition. The lesion of the nerve fibrils is irregularly dispersed and at the same time varies in intensity. No wonder in such circumstances that there should be the manifestation of disturbed coördinating power that is observed.

As a rule the ataxia in diabetic neuritis does not reach the advanced stage that is met with in some other forms of disease producing it. I have seen in some cases pronounced disablement from it but not the extreme disablement that may be met with in alcoholic neuritis or in tabes dorsalis. In a severe case of tabes there is a very characteristic kind of walk. The walk of neuritis, although ataxic, does not reach this. It is a common thing to find that the patient cannot satisfactorily get along without the aid of a stick or an umbrella or the arm of a friend. His gait is unsteady. He feels insecure upon his legs from a want of balancing power and requires the aid of something, and a very little will suffice, to steady him. At the beginning the condition is more or less like that of a slightly intoxicated person and repeatedly I have been told by patients that they have often felt conscious of walking so unsteadily as to lead to their pulling themselves together and walking at their best lest persons who were coming behind them might form an idea which they would not like to be entertained. Indeed, I am able to quote one case in which the circumstances were such as actually to call for my giving a certificate to rectify an erroneous conclusion that had been formed. The patient was a Nonconformist minister and a damaging report had become spread about with regard to him founded upon the resemblance of his gait to that of an intoxicated person.

It occasionally happens that a certain amount of ataxia is noticed by the patient without any of the sensory phenomena of neuritis being observable and in cases of a mixed nature the ataxia may stand out of proportion to the sensory phenomena. On the other hand, the converse may occur and with little or no ataxia there may be pronounced trouble of a sensory kind discernible. The two certainly are not always conjoined and the precise symptoms occurring obviously depend upon the particular nerve fibrils that constitute the seat of lesion. The nerves of the upper extremities are far less prone to be implicated than those of the lower. Whilst the gait is allied to that of tabes the neuritic patient, according to what I have seen, can maintain his equilibrium when standing with his feet together and his eyes shut to a far more perfect extent than can the tabetic. I have often submitted to this test diabetic patients suffering with ataxic symptoms and have, certainly as a rule, found that they stand with pretty nearly the same steadiness as a healthy person. It must be borne in mind in connexion with this matter that the muscular sense comes into play as one of the factors concerned and this may be at the foundation of the difference alluded to. Other points of difference may here be referred to. The Argyll-Robertson pupil phenomenon and the abnormal state of the rectal and vesical sphincters met with in connexion with tabes do not form a part of the motor derangement associated with neuritis.

Fibrillary contractions unattended with any sensation are sometimes visible over some of the muscles. They appear like wavy oscillations or twitchings under the skin and doubtless depend on an exciting effect exerted by the lesion on particular nerve fibrils.

The sensory symptoms of neuritis are with marked frequency met with as an accompaniment of diabetes and have often been misinterpreted by the medical practitioner. It has not been uncommon for them to have been put down to gout and I can recall from former experience more than one instance in which my advice has been sought for the diabetes and the suggestion has been made by the local medical attendant that as regards the gout I might leave this to him to look after. It is unfortunate if the symptoms fail to receive their proper interpretation, as treatment can render no service unless directed to the control of the diabetes which lies at the root of the trouble.

There is much variety in the symptoms complained of which is not to be wondered at seeing that the precise location and the extent of the lesion exert their influence on the result occurring. Phenomena arising from exalted activity on the one hand, or impaired activity on the other, are in different cases noticeable. Hyperæsthesia localised to different parts frequently exists. At other times there may be numbness, tingling, sensation of "pins and needles," and other paræsthesiæ spoken of as present. Sometimes the soles of the feet are extremely tender, rendering walking painful, or in other cases the patient may assert that he does not feel the ground properly or that it seems to him as though he were walking on pebbles or on pointed projections. Aching, deep-seated pains in the limbs, sometimes conjoined with "lightning" pains, may be experienced and it is often stated that there appears to be a tenderness of the flesh and bones. Usually the pain is worse at night than in the day and the patient may say that he finds it difficult to place his legs in a sufficiently comfortable position to enable him to get off to sleep. The tenderness of the limbs may be such as occasionally to lead to the employment of a pillow or something of the kind to escape from the distress occasioned by one leg resting on the other. Whilst it is infinitely more common to find the legs constituting the seat of neuritis than the upper limbs yet sometimes the latter are affected and much pain as a result may be experienced in them. I may state that I have also upon a few occasions come across waist girdle pain cases comparable to those met with in tabes. In one the distress occasioned was exceedingly severe.

The reflexes give the earliest sign of the impaired nerve power occasioned by neuritis and the knee reflex is the one that is ordinarily appealed to for information upon the point. As I have already stated, much was made of the knee phenomenon when it was first recognised as an accompaniment of diabetes and somewhat wild speculations were framed regarding its diagnostic and prognostic value. In reality it may be regarded as simply an issue of the toxic action of the sugar contaminating the system upon the nerves. Afferent sensory and efferent motor nerves with an intervening impulse-producing centre are involved in the operation of reflex activity and with such a working continuity needful it is not surprising that the phenomenon under consideration should stand in the position it does as an early sign of nerve implication arising from diabetes.

Absence of knee-jerk constitutes a very common accompaniment of diabetes. I do not know that any advantage is to be derived from saying more than this about the frequency of the association. The symptom is met with in all types of the disease where the passage of sugar to a pronounced extent has for some time occurred. In a chronic case of middle and after-middle life that has not been kept under proper control I consider it may be looked upon as exceptional for escape from loss of knee-jerk to occur. Duration seems to constitute a more important factor in connexion with the matter than intensity simply as such. The loss of knee-jerk may occur and the condition subsequently become rectified. This cannot be looked for unless amelioration as regards the diabetic state should take place. The symptom constituting, it may be considered, the primary effect of the toxic influence of the sugar traversing the system upon the nerves, so long as the sugar is there the cause continues in operation and maintains the condition, but if the sugar should be made to disappear the opportunity is given for the nerves to recover their natural state and thence for the symptom to subside. With a recurrence of sugar in the system a return of the symptom, as might reasonably be expected, is liable to occur.

(To be continued.)

THE TREATMENT OF HÆMORRHOIDS AND ALLIED CONDITIONS BY OSCILLATORY CURRENTS OF HIGH TENSION.

BASED ON AN EXPERIENCE OF 118 CASES.

BY T. J. BOKENHAM, M.R.C.S. ENG., L.R.C.P. LOND.

THERE are probably few individuals who reach middle age without having at some time suffered from some form of rectal congestion. The trouble is fortunately in most cases of brief duration and yields to one or other of the many domestic remedies for such conditions. Still, there remains a goodly proportion of sufferers who after a greater or lesser number of recurrences are compelled to seek advice. It is the fear of an operation being advised which deters many from doing so more promptly, and as the difficulty of affording relief is far less in recent cases than in those which have been allowed to become chronic it seems well to give careful consideration to any proposed method of treatment which tends to reduce the proportion of cases for which operative measures are usually required. Such an alternative was suggested in 1897 by Professor Doumer of Lille and the method has since been tried by many others both on the continent and in this country.

The advantages claimed by Doumer for his method of treatment of hæmorrhoids and sphincter fissures by currents of "high frequency"—viz., that the treatment is painless, that it involves no interference with ordinary occupations, and that it effects a cure in a very high percentage of cases treated—are so striking that should these claims be well founded the method certainly deserves to be more widely known. Analysis of the cases published by foreign observers shows a remarkable consensus of opinion in favour of the electric method of treatment, and it seems to have been admitted pretty generally by all who have put matters to a practical test that (1) Doumer's method is strikingly and quickly successful in cases of sphincter fissure and in healing the small fissures so often associated with hæmorrhoids; (2) [illegible] with simila[illegible] external and [illegible] not exhibit [illegible] tissues (it aff[illegible] conditions exi[illegible] panied by m[illegible] hæmorr[illegible] and at [illegible]

Duri[illegible] tunity of applying the treatment as advocated by Doumer in considerably over 100 cases of rectal trouble of varying severity so that I feel fully justified in presenting the following brief outline of the method itself and of the results obtained by it in my hands.

The method.—All that one needs is the group of transformers, condensers, oscillator, &c., generally known as a "high-frequency" installation, and a few metal and glass electrodes of various sizes and forms. Doumer seems to prefer an electrode of conical shape, but I think that the exact form is of minor importance so long as the electrode can be passed right through both sphincters and is of such a diameter that its surface can come into intimate contact with every portion of the area to be dealt with. The glass electrodes used have in some cases been filled with a conducting material such as granulated carbon or acidulated water, while in others they are of the "vacuum" type. Personally, I prefer these last, and in those which I now use the vacuum has been carried to such a point that, when excited, there is an abundant production of x rays. I find that an electrode of low vacuum is more unpleasant to the patient and also of less therapeutic efficacy. When metal electrodes are used currents of considerable quantity and very high potential can be applied to the patient without producing any local sensation beyond a feeling of slight warmth. In some instances I have in this manner employed a current of from 450 to 500 milliampères (measured by a hot-wire instrument) and of such a high potential that a thick spark over two inches long could be obtained on approaching any uncharged capacity to the patient's body. In using the glass electrodes a good deal of care is necessary and only comparatively small quantities (generally not exceeding from 100 to 150 milliampères) can be applied by their means without risk of causing both painful and undesirable local reactions. It is therefore necessary to attend carefully to the various points *of adjustment in order to secure the optimum conditions of* current intensity, pressure, and frequency of oscillation for the particular electrode and patient concerned. These are matters which can only be learnt by experience.

The duration of each application need seldom exceed 15 minutes at any one time. With a really powerful installation it is very easy to do too much and a local application of five minutes' duration will often suffice. The number of applications needed have varied considerably. Five or *six applications may suffice for the sound healing of many* cases of fissure, as also for the relief of recent hæmorrhoids, but in the more [illegible] over some three or four [illegible] cated. In these last c[illegible] electric treatment acts not only locally but also by a general influence exercised upon the processes of metabolism in the body.

In the following notes I have endeavoured to present in as concise a form as possible the data concerning the character of the cases treated by myself, the number of each kind, the duration of treatment, and the final result obtained. I may add that no case is included in which an interval of at least two months has not elapsed since the last electrical application and that wherever possible I have taken the precaution to ascertain the actual present condition of the patient.

1. *Simple fissures.*—Number of cases, 13. Number of applications, from 5 to 8. Result: Perfect healing in every case. Sphincter spasm was an almost constant feature in these cases and the prompt relief of this trouble was a very gratifying early result of the treatment.

2. *Acute or recent capillary piles.*—Number of cases, 25. Nu[illegible] from 6 to 11. Result: Cured, 14; [illegible]

3. [illegible] *es without marked hypertrophic changes.*—Number of cases, 31. Number of applications, from 9 to 18. Result: Cured, 6; greatly relieved, 20; improved, 5.

It is a satisfactory feature of all the cases comprising these three groups that they seldom required prolonged treatment, [illegible] almost at once, and that the [illegible] onstipation was generally [illegible] e local trouble.

[illegible] *irritable folds of skin but without marked venous congestion.*—Number of cases, 12 Number of applications, from 7 to 15. Result: Cured, none; greatly relieved, 6; improved, 6.

5. *Large venous external and internal piles.*—Number of cases, 16. Number of applications, from 12 to 30. Result: Improved 7; failures, 9. Of these cases I may mention that

two were cases of recurrence after operation: nearly all were of long standing and [illegible] with chronic gastro-intestinal disorders. For such cases electricity has not, in my hands at least, shown marked superiority over other and better known methods of treatment, although its use seems quite justifiable where operative treatment is positively refused.

6. *Post-partum cases (really instances of partial rectal prolapse with feeble sphincter muscle).*—Number of cases, 6. Number of applications, from 8 to 19. Result: Cured, 4; greatly relieved, 2. In all these cases the general tonic effect on the patient was quite as remarkable as the effect upon the local trouble.

7. *Pruritus ani, with moist eczematous condition of the parts.*—Number of cases, 15. Number of applications, from 4 to 7. Result: Cured in every case.

The above is a very brief outline of my results, but I trust that it may suffice to indicate in some measure the advantages and also the limitations of this variety of electrical treatment as applied to hæmorrhoids and other minor troubles of the rectum and anus. While the results as regards complete cures doubtless leave much to be desired they are still far superior to those obtained by any other local treatment short of operation. With experience also one is getting to select one's cases more carefully and there are many among those here recorded which I would not now undertake. It must also be remembered that hæmorrhoids are in many instances merely a symptom and result of hepatic or gastro-intestinal troubles. Where that is the case it will be idle to expect anything like a radical cure so long as the exciting cause remains.

Devonshire street, W.

ACCIDENTAL VACCINIA OF THE NASAL CAVITY.

By W. H. BOWEN, M B., B.S. LOND., F.R.C.S. ENG,
LATE CLINICAL ASSISTANT IN THE THROAT DEPARTMENT, GUY'S HOSPITAL.

THE following case is thought worthy of publication on account of the rarity of the condition as shown by previously reported cases, of which I have only been able to find one (*vide* infra).

A married woman, aged 28 years, attended the throat department for out-patients at Guy's Hospital on April 22nd, 1904, for a "sore nose and inflamed cheek." Her history was as follows. Her last baby had been vaccinated 14 days previously and had "taken well." On the 19th, 11 days after the vaccination of the infant and four days before I first saw her, she felt her nose to be "sore and itching." The same evening the right ala of the nose and the adjacent part of the cheek and upper lip began to swell and "lumps" began to form beneath the lower jaw on the same side. There was no discharge from the nose. On the 20th the nose was very painful and a discharge like a lot of water came from the right nostril and the face became more swollen. She went to the front surgery of the hospital, where it was found that the œdema of the face had spread so that both cheeks were swollen, red, tender to the touch, and felt to be "throbbing" by the patient. There was no definite limiting margin to the swelling. The upper and lower lids of the right eye were so œdematous as to meet over the eyeball, but on separation the conjunctiva was found unaffected. The glands in the submaxillary region were greatly enlarged and tender. Although she "went off her food" she was not sick and could do her housework. Her temperature while in the front surgery is said to have been 98° F. She was given hot boric fomentations to be used every four hours. On the 21st she felt much worse and could not eat or do her housework. The pain in the swollen face was worse and when she came to the hospital erysipelas was seriously discussed. She also complained on this day of something running down into the back of the throat which had a nasty smell.

In the absence of Mr. F J. Steward I saw her on the 22nd and found the condition as follows. She was a strong, healthy looking woman. The right cheek was very much swollen, including the lower lid, the right side of the nose, and the whole of the upper lip, spreading back to the temporal region and tragus of the ear behind and below over the lower jaw, gradually fusing with a large submaxillary swelling due to the enlarged glands in this region. There was no appreciable enlargement of the glands in the anterior or posterior triangles of the neck. The mucous membrane of the mouth was perfectly normal. The swelling, she said, was much less than it had been and it was [illegible] on the left cheek. This swelling was [illegible] œdema; it did not pit on pressure but [illegible] uch. The primary cause of the trouble was quickly found. Just within the right nostril on the floor and nearer the septum than the inferior meatus was a linear ulcer, perhaps a quarter of an inch in length, with its long axis from before back. This appearance was due to a swelling of unbroken mucous membrane on either side of a linear excoriation. It showed no characteristic signs at all and even when the mucus, of which there was a great quantity, had been cleared away it would have been extremely difficult to decide upon its nature from its appearance. Fortunately additional evidence was present in the form of a small greyish area situated just below the columna of about the size of a large pin-head surrounded by a red areola. This was, undoubtedly, the result of an accidental vaccination, and I had no doubt at all that the intranasal condition was of the same nature. As mentioned above her baby had been vaccinated a fortnight before. She denied, however, that the vesicles on the baby's arm had ever been broken and said that the scabs which had formed were still intact. She never remembered the baby scratching her with its nails, but she was suckling the infant. Anyone who has watched a baby either taking the breast or being carried in the mother's lap, remembering the restless way in which babies "claw" at everything about and with special frequency the mother's face, will readily understand the ease with which inoculation is brought about. The mother had not been vaccinated since she was a baby. She was advised to continue the hot boric fomentations to the right side of the face and was ordered chinosol, 1 in 1000, to syringe the rig[illegible]. Mr. Steward saw her on the [illegible] diagnosis. On this day the [illegible] eyish surface which, as pointed out by Mr. Steward at the time, is almost typical of the condition. I watched the patient subsequently until the 26th, when the vesicle inside the nose was scabbing over, and realising that she was better she did not attend further.

The only other case which I could find of accidental vaccinia of the nasal cavity was reported in the *Birmingham Medical Review* for 1903 (vol. i., p. 390) under the title of "Two Cases of Accidental Vaccination," by Dr. E. A. Sadler. In this case there were fissures found at the right ala of the nose. The patient was a woman, aged 32 years, and her baby had been vaccinated three weeks before. The mother had not been vaccinated since infancy.

Of 46 other cases of accidental vaccination which I found reported in various journals, 31 were on the face. (Of these there were on the cheek, seven; on the eyelids or conjunctiva, or both, 11; on the chin, two; and on the lips, three.) One case is reported on the tongue, eight were situated on the trunk (including the breast, the buttocks, the penis, and the vulva), and four on the limbs. The diagnosis has usually been easy owing to the typical appearance of the vesicles. As might be expected it occurs far more frequently in women than in men, but often occurs in children, especially those who sleep with recently vaccinated brothers or sisters but have themselves either never been vaccinated or have never "taken," whilst it is not infrequent in young girls who nurse a recently vaccinated baby and not having been revaccinated themselves are liable to feel the full effects of reinoculation. The signs and symptoms are similar to those following the ordinary inoculation of the arm, but one case is reported of the loss of the eye from accidental inoculation of the conjunctiva. The inoculation is frequently multiple though seldom more than three vesicles form. One extraordinary case is reported of inoculation on eczematous surfaces where 400 separate vesicles were found. This occurred in a boy, aged two years, whose infant brother had recently been vaccinated. The two children played and slept together. The constitutional symptoms in this case were not very marked.

Below is appended a list of references to cases of accidental vaccination. No case of accidental vaccinia of the nose was found either in the Proceedings of the Laryngological Society or in the *Journal of Laryngology, Rhinology, and Otology*.

THE PRESENCE OF BACTERIA IN THE ORGANS OF HEALTHY ANIMALS.

BY H. DE R. MORGAN, M.A. OXON., M.R.C.S. ENG., L.R.C.P. LOND., D.P.H. CANTAB.

(From the Bacteriological Department of the Lister Institute of Preventive Medicine.)

THE possible occurrence of bacteria in the organs of normal animals has been made on many occasions a subject of inquiry. The question is obviously an important one whether considered clinically or scientifically. The interior of the healthy organism has usually been regarded as free from bacteria and the researches of Pasteur and of Duclaux [illegible] A number of observers have [illegible] confirmatory evidence. On the other hand, a recent research published by Ford[1] furnishes, according to this author, experimental proof that normal organs do, as a matter of fact, contain bacteria. The paper gives a valuable *résumé* of the literature on the subject and from this I will quote before dealing with the author's own experiments. Meissner found no bacteria capable of development in the tissues of the healthy animal, whilst Zweifel concluded that germs were habitually present but of an anaerobic character and limited in their capacity for development by the amount of oxygen in the blood stream. The researches of Hauser led to a negative result, the microscopic examination and the cultures made from healthy tissues showing them to be free from bacteria in every case. Welch only found the colon bacillus in the internal organs in cases of distinct lesion of the intestinal mucosa and he further states that this bacillus does not invade the blood [illegible] tion. Neisser, [illegible] tamination, ren [illegible] and mesentery [illegible] tissues in nutri [illegible] at the end of two days were invariably found to be sterile. Neisser concludes "that under normal conditions no bacteria are present in the lymph or blood stream." He found, on the other hand, that after producing artificial lesions of the intestines and feeding the animals experimented on with cultures of various micro-organisms, the organs of such animals contained either these bacteria or representatives of the intestinal flora. Opitz carried out experiments on cattle in the abattoir at Breslau. Portions of the mesenteric glands from cattle were carefully sterilised on the surface and small pieces were then excised and cultivated upon agar and gelatin plates. It was found that at the end of three [illegible] majority of the tissues [illegible] l from a small number [illegible] aring organisms—e.g., [illegible] that the mesenteric [illegible] and that bacteria do [illegible]

Ford emphasises the fact th [illegible] the incubation of the tissues [illegible] for 17 days and that organisms were found to grow in the cultures as late as the seventeenth day. Neisser and Opitz, on the other hand, drew their conclusions from specimens which had only been incubated for a period of three days. Ford in a series of experiments made with 30 organs removed from rabbits found that 66 per cent. contained bacteria cultivable on agar, gelatin, and broth, whilst with 18 organs removed from guinea-pigs positive results were obtained in 61 per cent. The bacteria found in each case were identical and appeared in the culture media on the seventh day. It was thus only after a lapse of seven days that the organisms detected by Ford escaped from the organs which contained them and appeared as a growth in the culture soil. The bacteria found were staphylococcus albus and aureus, bacillus mesentericus, bacillus proteus, bacillus subtilis, and bacillus coli communis.

The organs of cats showed a bacterial flora different from that of the rabbits and guinea-pigs. Of 18 organs from the cat positive results were obtained in about 77 per cent. Staphylococci and colon bacilli were detected but not the bacillus subtilis or the bacillus mesentericus. The bacillus proteus, bacillus megatherium, and bacillus mycoides were found as well as two spore-bearing bacilli detected in the broth cultures. These spore-bearing forms along with the bacillus megatherium and bacillus mycoides and at times bacillus Zopfii were also present in the organs of dogs. The experiments of Ford showed that out of 96 organs taken from 34 animals 69 per cent. contained bacteria and that less than 30 per cent were sterile. It appeared advisable in view of the exceptional character of these results to repeat the experiments and I will now briefly describe the methods which I adopted and the results. Every precaution was taken in the course of the experiments to avoid aerial or other accidental contamination. A rabbit was killed, the skin was deflected from a central linear incision, and the abdominal muscles were seared with a red-hot iron. The abdomen was opened with a sterilised scalpel and ten cubic centimetres of peptone broth were poured over the intestines and immediately drawn up, together with any peritoneal fluid, by means of a sterile syringe. The fluid obtained in this way was placed in a sterile tube for subsequent cultivation. The intestines were next drawn aside by sterile glass rods and the exposed organs or portions were removed—viz., the kidney, the suprarenals, the spleen, the liver, and a few of the mesenteric glands. Each organ was quickly passed through the flame of a Bunsen burner and then divided, one portion being dropped into a flask of nutrient broth and the other into melted agar cooled down to 45° C. The organs in the broth were broken up with a sterilised knife and both broth and agar were incubated at blood heat. The broth cultures were employed to test for aerobic and the agar cultures for the growth of anaerobic micro-organisms. After 17 days' incubation portions of the organs planted in the agar were removed with a platinum needle, transferred to broth tubes, and kept for several days at blood heat under anaerobic conditions in a modified Buchner's tube and eventually examined for bacterial growth. From the organs in broth, subcultures were made in fresh broth every third day, care being taken to avoid contamination. These subcultures were kept at blood heat, and in the event of no growth occurring were reinoculated on the second or third day. 80 organs and the peritoneal fluid from ten rabbits were tested in the above manner. Growths were obtained from 23 organs in the aerobic broth cultures and from one rabbit two organs gave a growth of the colon bacillus. This latter result was, however, probably due to an accidental injury to the intestine and a consequent contamination of the surface of the organs. In no case was a growth of the colon bacillus obtained from an animal with uninjured intestines. The bacteria present in the broth cultures were non-pathogenic forms and their intraperitoneal injection in rabbits proved harmless. They consisted mostly of such common types as the bacillus mesentericus vulgatus along with a number of other non-pathogenic spore-bearing forms. These organisms never appeared later than the third day in the cultures and differed in no respect from similar organisms planted *per se* in peptone broth. From the anaerobic agar cultures no growth was obtained in any instance and I was unable to confirm Zweifel's [illegible] anaerobic organisms in the [illegible] xperiments were made with [illegible] a similar number from the [illegible] pathogenic forms were obta[illegible] ns in each case.

---

[1] The Bacteriology of Normal Organs, Journal of Hygiene, 1901.

On comparing these results with those of Ford, one is struck with the similarity of the organisms found and with the fact that the percentage is much lower than that obtained by him. The number of organs tested by myself was 80 and excluding the two cultures of the colon bacillus obtained in the case of one rabbit, the percentage of positive results is 26·2 per cent., or with the above-named cultures 28·7 per cent., as against 66 per cent. in the case of 30 organs tested by Ford. It is difficult to determine whether the bacteria found were really contained in the organs or not, although every care was taken to avoid contamination. It is well known that organisms of the types detected are ubiquitous in the air and it is quite possible that the germs or their spores adhered to the moist surfaces of the exposed organs during the post-mortem examination. By way of settling this point a certain number of the animal organs were sterilised in the autoclave at a temperature of 128° C. for 20 minutes. This effectually destroyed any bacteria or their spores that might happen to be present either inside or on the surface of the organs. The organs were then placed in sterile Petri dishes in the neighbourhood of an animal on which a post-mortem examination was about to be made and exposed to the air for five or ten minutes. They were next passed through the flame, placed in broth, and incubated at blood heat for two days. In short, they were subjected to exactly the same treatment as the fresh organs in the former experiments. In the case of the organs which had been exposed for ten minutes to the air of the post-mortem room only one out of five proved sterile, whilst of those exposed for five minutes only one out of seven organs was found to be sterile. The organisms found were similar to those met with in the previous experiments—viz., staphylococci and non-pathogenic saprophytic bacilli. From these experiments with autoclaved organs the presumption is strong that the organisms detected in the previous experiments were not really contained within the tissues but that they had, in spite of the precautions taken, fallen on the surface of the organs during some part of the manipulations. In Ford's experiments the frequent opening of the test-tubes may have led to similar contamination.

It is rather a significant fact that in my experiments no growth was obtained from the spleen, which was always removed first, while the mesenteric glands, which were removed last, gave the highest percentage of positive results—viz., seven out of ten glands tested. It might, of course, be suggested that the mesenteric glands form the natural channel for germs passing out of the intestine and that their presence in these glands could thus be accounted for. An injection of five cubic centimetres of broth culture of the organisms intraperitoneally into the same species of animal gave rise to no apparent symptoms or even temporary illness. The following table gives the results of the broth cultivations from the organs of ten rabbits :—

No. of rabbit.	Liver.	Heart.	Right kidney.	Left kidney.	Spleen.	Mesenteric glands.	Suprarenal.	Peritoneal fluid.	Pathogenicity.
1	—	—	—	—	—	C. & B.	—	—	—
2	—	—	—	—	—	—	—	B.	—
3	—	—	B.	—	—	B.	B.	—	—

6	—	—	—	C.	—	B.	—	B.	—
7	C.	—	—	C.	—	B.	C.	B.	—
8	—	—	—	—	—	B.	—	C.	—
9	B. coli.	—	—	—	—	B. coli.	—	C.	B.coli + C. −
10	—	—	—	—	—	—	—	—	—

B. = bacillus; C. = coccus.

These results lead to the following conclusions: 1. That normal organs do not contain pathogenic bacteria. 2. That the presence of non-pathogenic organisms in the cultures is probably due to accidental contamination. These conclusions coincide with those arrived at by Meissner, Hauser, Neisser, Welch, and Opitz. After the above experiments were finished my attention was drawn to an article by A. Wrzosek[2] who found that on adding cultures of the bacillus prodigiosus, bacillus fluorescens, bacillus violaceus, and bacillus pyocyaneus to the food of certain animals and killing these animals from five to 20 days afterwards, these organisms were found in the mesenteric glands, lungs, liver, muscles, and spleen in from 30 to 50 per cent. of the animals. Wrzosek accounts for the small percentage of animals in which they were found by the supposition that the phagocytes destroy organisms in a very short time.

ON NON-FLAGELLATE TYPHOID BACILLI.

BY J. W. W. STEPHENS, M.D. CANTAB.,
WALTER MYERS LECTURER IN TROPICAL MEDICINE, UNIVERSITY OF LIVERPOOL.

THE method used by me for staining flagella with silver already described elsewhere[1] is a modification and simplification of van Ermengem's method. 1. The mordant consists of osmic acid 2 per cent., 1 part; tannin 20 per cent., 2 parts. (I find that ferrous sulphate instead of osmic acid will also give positive results, but I have not so far experimented further in this direction.) This is allowed to act for from half an hour to one hour or longer. 2. The silver solution is 0·2 per cent. silver nitrate. 3. Ammonium tannate solution. A quantity in a watch-glass sufficient for staining one slide is freshly made thus: tannin 20 per cent., 0·2 cubic centimetre; equal parts of strong ammonia and water, 1 cubic centimetre. The slides are cleaned by wiping with a cloth and then heating well on a clean wire gauze over the Bunsen flame. The emulsion is made by plunging the culture below the surface of the water in a small test-tube and allowing it gradually to dissolve off. The emulsion is made faintly milky. With a pipette I flood the cool slides with the emulsion and then allow it to drain off. When dry the slides are put in the mordant for from half an hour to one hour. They are then washed with water. To stain, a few drops of silver are put on the slide and then a few drops of ammonium tannate and the slide is rocked to and fro for a few minutes. Then I wash in water and repeat the staining three or four times. I had used this method for some time and had constantly got positive results with it, so that I felt secure in describing it last year. Shortly after having done so I was much surprised at being unable to stain flagella in a culture of typhoid bacilli which I had used for demonstrating the method. I at first thought that the method must, after all, be uncertain in spite of my previous constant successes and it was only after a considerable time that I began to suspect the cultures. Three different strains of typhoid bacilli all gave me no result. I had not a single success in many months of trials. I eventually examined these cultures in a hanging drop and found that none exhibited the characteristic active movements of typhoid bacilli but they only showed slight trembling movements. I found on consulting the most recent literature that this loss of motility was a recognised fact but I could find no statement that this was associated with a loss of flagella. It seemed to me possible that this was the cause of my failures. I procured consequently a fresh strain of typhoid bacilli recently isolated from a patient. (My previous cultures had all been very old laboratory strains.) This showed typical motility and on proceeding to stain it with the method I had been using for months without success the result was at once positive. I thought therefore I was justified in concluding that my failure to stain the old cultures was due to the fact that there were no flagella there to stain. I took further one of these cultures and passed it through a guinea-pig and isolated the bacillus from the heart's blood. The bacillus was now motile and gave the cultural characters of typhoid. I was able at the first and at all subsequent attempts to show that it now possessed flagella (the old culture still remains negative). I believe then that I am justified in concluding that we may have non-flagellate typhoid bacilli.

The bearings of this observation may be of interest. 1. It may be necessary to pass a bacillus—e.g., bacillus dysenteriæ (Shiga)—through an animal or to examine freshly isolated bacilli before we can be quite certain that they do not [illegible] in this phenomenon.

---

[1] Thompson Yates and Johnston Laboratories Report, vol. v., Part I., 1903.

Note.—For detecting flagella it is simplest to make a smear of the culture with a thin glass filament in the same way as a blood film, a trace of water being used for dilution. These smears when stained show the presence of flagella beautifully.

Liverpool.

A CASE OF TRAUMATIC TETANUS; RECOVERY.

BY HAROLD COLLINSON, M.B., B.S. LOND., F.R.C.S. ENG.,
RESIDENT SURGICAL OFFICER AT THE GENERAL INFIRMARY, LEEDS.

THE patient, a man, aged 25 years, was admitted to the General Infirmary, Leeds, under the care of Mr. Edward Ward, on Jan. 7th, 1903, suffering from an extensive lacerated wound of the left hand and forearm, together with compound fractures of most of the phalanges and metacarpal bones. These injuries had been caused by a "brushing" machine, one of those used in the preparation of hides. Two fingers were amputated and the wounds were partially closed after careful cleansing. A considerable amount of sloughing of the bruised tissues occurred during the next few days and the limb was dressed with boric fomentations. On Jan. 15th the temperature was normal, the wound was clean, and all seemed to be satisfactory. During the evening of the 18th—11 days after the injury—he complained of slight stiffness of the jaw and the back of the neck and also of shooting pains in the injured arm. Next morning there was distinct rigidity of the masseters and posterior cervical muscles and he was sweating profusely.

A definite diagnosis of tetanus having been made a subcutaneous injection of 20 cubic centimetres of antitetanic serum was administered at noon and permission to amputate the limb was sought for; this, however, was refused, so the wound was opened up, freely syringed out, and oxygen was applied for five minutes every quarter of an hour. Chloral hydrate in doses of 20 grains was also ordered to be given every four hours. At 11 P.M. the temperature was 100·8° F. and the pulse was 112; the patient was lying wide awake, sweating profusely, and with an anxious expression. The teeth could be separated barely a quarter of an inch. His speech was slow and indistinct and was accompanied by painful contractions of the facial muscles with a well-marked risus sardonicus. The posterior cervical and lumbar muscles were rigid and the same condition was present, but scarcely so marked, in those of the abdominal wall. Another injection of 10 cubic centimetres of serum was given and permission was again sought for amputation. This was at last obtained and at 3 A.M. on Jan. 20th the limb was amputated through the condyles of the humerus, a lower site being impossible owing to the extensive laceration of the skin of the forearm. Just before the anæsthetic was administered the patient was seized with a tetanic convulsion lasting about 30 seconds with marked opisthotonos. This was the only severe convulsive seizure that occurred. At 6 A.M. the temperature was normal and the pulse was 100. At 11 A.M. he appeared slightly better and had slept naturally; the sweating was less although the muscular rigidity was quite as marked. Another injection of serum (10 cubic centimetres) was given and repeated in the evening. In the afternoon the patient slept well and the symptoms did not progress. Chloral hydrate in doses of 20 grains was administered every four hours.

During the next two days the patient's condition remained very much the same; considerable quantities of fluid food were taken by means of a rubber tube passed through a gap in the teeth and the injection of serum was repeated twice on the 21st but omitted on the 22nd. Any sudden noise was liable to cause a temporary increase in the rigidity but there were no actual convulsions. The chloral was continued and was very effectual in dulling his sensibility and procuring sleep. On the 23rd the pulse was less frequent and the patient was drowsy, so the dose of chloral (20 grains) was administered at intervals of six, instead of four hours, but the injections of serum were recommenced twice a day. At 11.30 P.M. on the 24th the muscular rigidity was more marked with considerable arching of the lumbar spine and the pulse had risen to 92. Chloral (20 grains) was again given every four hours. On the 25th he was not nearly so well and sweated profusely; during the night there were four or five slight convulsive attacks lasting a few seconds only and exceedingly painful. The dose of chloral was increased to 25 grains but the serum was discontinued. At 11.30 P.M. on the 26th he was much better, had slept well, and the muscular rigidity was much less marked. During the next 48 hours the improvement was maintained, but on the 28th he was so drowsy and stupid that the chloral was discontinued *pro tem.* This was followed by an increase of the muscular rigidity and arching of the lumbar spine and so 20 grains of chloral were again given every six hours. During the next week improvement continued very slowly and the chloral was gradually reduced to one dose at night. On Feb. 9th the abdominal muscles again became [illegible] was again increased. By the 15th [illegible]d he was *allowed to get up for* [illegible] by a bad night and considerable sweating and in consequence he was kept in bed for a few days longer. He was discharged on Feb. 28th quite well.

The foregoing case occupies a position intermediate between that of acute tetanus and the variety which has been designated "chronic" tetanus and would be best described as "subacute." The period of incubation was comparatively long, 11 days, and the duration of symptoms was one month. The rapidity with which the symptoms progressed during the first 24 hours of the attack was in marked contrast to the stationary condition which they assumed after amputation of the limb and the exhibition of chloral and antitetanic serum and it was only during the initial stage that the case could be described as acute.

With regard to the effect of treatment, one is confronted with the fact that in a certain proportion of subacute or "chronic" cases recovery is spontaneous and one cannot, of course, state definitely that in this particular instance amputation of the arm would not have sufficed. I am, however, inclined to attribute a considerable share in the favourable termination of the case to the effect of the free administration of chloral, for, as has been seen, the reduction of the dose was on one or two occasions followed by a distinct exacerbation of the symptoms. The injections of antitetanic serum did not produce any appreciable effect and in two other cases of acute tetanus which I have seen its administration was also futile, although in one case it was injected into the cerebral ventricle.

My thanks are due to Mr. Ward for permission to record the case.

Leeds.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE MODE OF INFECTION IN TUBERCULOSIS.

BY J. M. FORTESCUE-BRICKDALE, M.A., M.D. OXON.,
REGISTRAR AND PATHOLOGIST TO THE ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN, BRISTOL.

THE importance of the site of the oldest lesion as determining the mode of infection in tuberculosis is very generally assumed and the acknowledged rarity of primary abdominal tuberculosis in children, as seen in post-mortem records, is adduced as one argument against the frequency of infection by means of milk from tuberculous cows. In this connexion the following case in which I recently performed a necropsy is, I think, suggestive.

The child, a girl, aged five years, was born of a mother who was suffering from phthisis and was suckled till within a week of the death of the mother which occurred when the child was ten months old. The home surroundings were said to be healthy. The patient was first admitted to the Royal Hospital for Sick Children and Women, Bristol, in June, 1900 (at two years of age), for otorrhœa, under the care of Mr. H. Elwin Harris, to whom I am indebted for leave to publish the clinical history. She was then found to have phlyctenular conjunctivitis (worse in the left eye), left facial paralysis, and a foul, purulent, sanious discharge from the left ear. She was thin, anæmic, and of sallow complexion. The spleen and liver could be felt below the ribs and her teeth were carious. There were also signs of consolidation at both apices. On Oct. 6th Mr. Harris operated on the left ear in the usual manner. In January, 1901, Klebs-Löffler bacilli were found in the nose and throat, and these were continuously present till August, when they were found to be non-virulent. The child was discharged much improved in general condition in October. In November she was again admitted for necrosis of the jaw, which was successfully operated on by Mr. Harris and she was discharged in the following January (1902). There is no note of the then pulmonary condition. On August 18th, 1903, she was admitted for the third time for recurrence of the discharge from the ear. She was thin and anæmic but there were no physical signs in the lungs. She developed, however, symptoms of intracranial trouble and Mr. Harris explored the temporo-sphenoidal lobe and opened an abscess containing green offensive pus. With drainage improvement occurred but 14 days after operation pyrexia and drowsiness set in and in spite of a free escape of pus she died on Oct. 1st.

Post mortem the cerebral sinuses were found to be healthy. There was a little basal meningitis, mainly on the pons, but there were no tubercles. There were numerous deep-seated abscesses in the left temporo-sphenoidal lobe and a calcareous mass about two millimetres long in the right lobe of the cerebellum. There were some fairly recent adhesions of the pleuræ; the apices of both lungs were puckered and scarred but showed no active disease. The tracheal, bronchial, and superior and inferior mediastinal glands were enlarged, hard, and yellow, but not much matted together. In the intestine a few of Peyer's patches were congested but there was no ulceration or scarring. A few mesenteric glands showed tuberculous foci. The liver appeared fatty. There was no lardaceous disease of any organ. The other organs were healthy.

It is unfortunate that we have no bacteriological data as to the mother's milk or the original discharge from the left ear. It is therefore possible to suppose that the earliest lesion was in this situation and that no infection by milk took place. This, perhaps, would be supported by Dr. Allan Macfadyen's recent experiments on monkeys, which showed a tendency of human tubercle bacilli to produce intestinal ulcerations when ingested.[1] The calcareous nodule, though on the opposite side, might be considered to support this view. But it is at least possible that the original ear trouble was due to the Klebs-Löffler bacilli and I cannot help feeling that the chances that the mother's milk contained tubercle bacilli are great. If this was so it follows that the absence of a "primary" manifestation of tuberculosis in the abdomen does not necessarily exclude the possibility of infection by milk.

Bristol.

TREATMENT OF CHRONIC ULCER OF THE LEG OF LONG STANDING.

By HORATIO W. A. COWAN, M.B., C.M. ABERD.

AT the beginning of the present year I was called to a woman, aged 54 years, who had had a chronic sloughing ulcer for 22 years situated on the outside of the left leg, some ten inches long and three inches wide, with indurated edges and some thrombosis of the veins of the inside of the knee. Having first cleansed the ulcer with charcoal poultices for two days I applied wet buttercloth and then spread antiphlogistine over it after which cotton wool and a bandage were put on. This was done every day by the patient's friends for four months. The ulcer is now quite healed over and the induration is all gone. She is able to resume her ordinary housework. I publish this case in the hope that it might be useful to others as Unna's paste and all sorts of methods had been previously tried. I may say that I have no personal interest in antiphlogistine.

METROPOLITAN HOSPITAL.

A CASE OF BRONCHIECTASIS TREATED BY EXTERNAL DRAINAGE.

(Under the care of Dr. A. T. DAVIES.)

FOR the notes of the case we are indebted to Mr. A. Denham White, senior house physician.

The patient, a man, aged 32 years, was admitted into the Metropolitan Hospital on Jan. 14th, 1904. For ten days preceding his admission he had suffered from cough accompanied by profuse expectoration and gradually increasing pain in the right side. Two days before admission he became much worse. His breathing was more difficult and the expectoration became very offensive. Previously to the onset of this illness he had been a healthy man. There was no history indicative of phthisis affecting either himself or his family. When admitted the patient was extremely ill, the face was drawn, and the complexion was sallow. His temperature was 101° F., the pulse was 124, and the respirations were 36 to the minute. His breath was very foul and he brought up large quantities of muco-purulent material. Physical examination revealed the presence of extremely marked general bronchitis, in addition to which there was dulness on the right side extending in front from the third intercostal space and reaching the angle of the scapula behind. The breath sounds all over this area were very faint and assumed a bronchial character in the apex of the axilla. Tactile vocal vibrations, though present, were very feeble and voice sounds were very poorly conducted. The signs of bronchitis over the rest of the lung were very evident. There was no cardiac dilation and the urine was free from albumin. Microscopical examination of the expectoration failed to reveal the presence of tubercle bacilli either at the time of admission or during the subsequent course of the case. Large quantities of various pyogenic organisms were, however, seen. On the following day he was no better; he sat up in bed breathing 40 to the minute, and when moved for purposes of examination or for any other reason he was seized with a violent paroxysm of coughing which lasted for several minutes during which time he brought up large quantities of foul muco-purulent sputum. A definite diagnosis was not then arrived at, but it was thought that the patient was either expectorating a purulent pleural effusion or had a bronchiectasis. No operative treatment was then decided on but an antiseptic inhalation of creasote and carbolic acid was given together with stimulants.

During the next 48 hours the signs of effusion steadily diminished till by Jan 18th, four days after admission, the signs of fluid had disappeared, though he continued to expectorate a good deal of muco-pus and the bronchitis persisted. At this time the right side of the thorax was quite resonant, though the breath sounds remained weaker and vocal vibrations were feeble; the paroxysms of coughing were also less violent. The temperature ranged between 100° and 101° F. and the respirations between 36 and 40. On the 20th slight dulness was again noted at the right base behind and this slowly increased till by the 26th, the amount of purulent sputum increasing *pari passu*, the physical signs were as follows. At the right back there was dulness up to the angle of the scapula with very much weakened breath sounds. There was no bronchial breathing but whispered pectoriloquy could be

---

[1] THE LANCET, Sept. 12th, 1903, p. 704.

[illegible] the fifth rib in the mid-axillary line being chosen and about one inch was removed. The lung was found to be pressed tightly against and adherent to the chest wall, entirely obliterating the pleural cavity. A needle was therefore passed into the lung for a distance of three inches and pus was again withdrawn. A large probe was then passed in the same direction into the lung and appeared to be in a large cavity in which the bent end of the probe [illegible] withdrawing the probe pus [illegible] of bleeding from the lung [illegible] the passage was undertaken till the following day, when the opening was enlarged with forceps and a small tube was inserted, nearly a pint of pus escaping. As a result of this treatment the patient's improvement was marked. Within 36 hours all muco-purulent expectorations had ceased, the respirations fell from 40 to 22 per minute, and the cough nearly ceased. Three days af[illegible]perature became normal and a [illegible] was seen in the pulse rate. Th[illegible] much better, the appetite returned, and the patient began to gain weight.

At this time iodine baths were being given for half an hour daily with the result that the discharge though remaining profuse was far less offensive. The improvement continued steadily until Feb. 13th when the temperature again began to rise, the expectoration of foul pus recommenced, and the wound simultaneously ceased to procure effective drainage. Accordingly on the 17th, three weeks after the first operation, a further portion of the same rib was excised under chloroform, the lung was freely incised with but little hæmorrhage resulting, and a full-size drainage-tube was inserted. The cavity appeared to be about two and a half inches in diameter and the walls were soft and spongy; several ounces of pus were evacuated. For the three days following the operation the symptoms improved, the temperature fell to normal, expectoration ceased, and the discharge became sweet. About this time the bronchitis began to clear up. Since then the improvement had continued, the discharge had slowly become less, and the cavity had diminished in size. As regards physical signs there remained dulness and extremely weak breath sounds below the level of the operation wound but the tactile vocal vibrations were increased. Above the wound the note was good and air entry and breath sounds were natural and the left lung was also natural. The patient made an uninterrupted recovery and was sent to a convalescent home on May 1st. A sinus about two inches long admitting a small probe still remained but there was no discharge and the patient when last seen on June 1st was in excellent health. He had no cough or pain and had regained his weight and strength. The only drugs given internally were the usual stimulants and expectorants, together with ichthyol in capsules containing ten grains three times a day. For permission to publish the above notes Mr. Denham White is indebted to the courtesy of Dr. Davies.

WEST NORFOLK AND LYNN HOSPITAL, KING'S LYNN.

A CASE OF LACERATION OF THE BRAIN BY CONTRECOUP.

(Under the care of Mr. H. O. Allinson.)

For the notes of the case we are indebted to Mr. Basil H. Pain, house surgeon.

On June 14th at 1 P.M. a man, aged 46 years, was taken to the West Norfolk and Lynn Hospital on an ambulance with a history of having fallen into the hold, some 15 feet deep, of a vessel unloading in the docks, and that he fell striking the back of his head on a steel plate. On removing the hood of the ambulance stretcher the man was seen lying on his left side, having recently vomited. His pulse was slow (56) and he resisted attempts to get a view of his pupils. He tried to get off the stretcher but did not speak. He was taken into the ward and an examination failed to reveal any signs of external injury. He was cold and collapsed when admitted but soon rallied. He vomited three times within the next two hours. A little [illegible] no paralysis could anywhere be discovered. The knee-jerks were well marked, possibly increased, and his arms and legs were held stiffly. On lightly stroking the plantar surfaces of the feet the legs were quickly withdrawn. There was no discharge from the nose or ears. The eyes were next examined but were unable to afford any assistance in diagnosis, for both showed extensive signs of old iritis, the pupils being eccentric, and in the left eye there was a large coloboma, apparently due to operative interference many years ago. Throughout the night he was very restless, a male attendant being required to keep him in bed. His pulse at 10 P.M. was 100, the respirations were 26, and the temperature was 99·6° F. The next morning a diffuse swelling was apparent over the region of the lambdoid suture. He was able to swallow fluids but never spoke. At 10 A.M. his pulse was 64, the respirations were 16, and the temperature was 99·6°. At 2 P.M. his temperature had risen to 102·4°, the pulse was 100, and the respirations were 24. At 3.30 P.M. he vomited and had great dyspnœa and cyanosis. Tongue forceps and gag being used, free air entry was obtained, but the respirations became slower and more laboured, and finally ceased, his heart continuing to beat about a minute after all respirations had ceased.

Necropsy.—A post-mortem examination revealed a small hæmatoma beneath the aponeurosis of the occipito-frontalis in the middle line in the region of the lambdoid suture. No depressed or fissured fracture could be made out on the surface of the skull, so the skull-cap was removed in the usual manner. The dura mater beneath was not torn and looked normal. The superior longitudinal sinus was empty. On stripping the dura mater off the brain, the blood-vessels running in all the sulci were seen to be much engorged and anteriorly the superior and middle frontal convolutions were reduced to pulp and mixed with blood. The base of the brain was free from injury and likewise the spinal cord. The ventricles of the brain appeared to be natural. An examina- [illegible] skull were clearly marked out by a dark line of extravasated blood in the sutures, suggesting at first glance a fractured base, but on comparing this line with the sutures on the [illegible] a mater from the [illegible] re was no fracture [illegible] found except the small bony projection between the two parietals mentioned above.

Remarks by Mr Pain.—The points of the case which I venture to think are interesting are: 1. The patient's pupils being eccentric and a coloboma present in the left eye they afforded no aid in diagnosis of the brain lesion. 2. A specimen of urine voided some ten hours before death reduced Fehling's solution. The urine was boiled with freshly prepared Fehling's solution. No reduction took place till cooling began, when the whole suddenly turned to yellow, then to red, and cupric oxide was deposited. Some reducing substance was evidently present in the urine, the specific gravity of which was 1014 and contained a trace of albumin. 3. The injury to the frontal lobes, by what I take to be injury due to contrecoup. For permission to publish these notes I am indebted to Mr. Allinson, under whose care the case was placed.

MELBOURNE HOSPITAL.

A CASE OF GENERAL PANCREATITIS WITH JAUNDICE; CHOLECYSTENTEROSTOMY; RECOVERY.

(Under the care of Dr. W. Moore.)

A married woman, aged 25 years, came under the care of Dr. Moore first in May, 1902, suffering from jaundice with a large tumour in the left hypochondrium and the epigastrium. The tumour was rounded, hard, non-fluctuating, and freely moveable, the percussion note over it was dull, and the dulness was continuous with that of the liver. The tumour was first noticed six years previously, when she had a sharp catching pain in the left side; since then the pain had been dull and more or less persistent. About the beginning of May, 1902, she had an attack of severe pain in the epigastrium and afterwards became markedly jaundiced.

She was then about two months pregnant. Hydatid of the liver was diagnosed and operation was advised. Operation was performed on May 13th. Dr. W. R. Boyd administered chloroform and Dr. A. S. Aitchison, under whose care the patient had been, assisted. A mid-line incision above the umbilicus at once revealed a hydatid cyst in the left lobe of the liver. The cyst contained some bile-stained fluid and a large number of daughter cysts, some whole, and some collapsed. The edges of the incision into the cyst were sutured to the upper part of the abdominal incision, the lower part of which was accurately sutured. A large rubber drain-tube was inserted into the cyst cavity. The patient made a somewhat slow recovery, not being able to leave hospital until June 29th, nearly seven weeks after the operation. A great many cysts drained away and the "adventitia" or fibrous outer wall of the sac also died and came away as a large slough. The jaundice gradually disappeared. The patient had a good deal of pain in the right side and vomited frequently, but before the end of July, 1902, she had quite recovered and was then in good health.

Dr. Moore was again asked to see the patient on March 10th, 1904. She was then very ill, was jaundiced, and was vomiting frequently and complaining of severe pain in the epigastrium. She stated that after her illness in May, 1902, she had remained very well until January, 1903, just before her confinement, when she had an attack of severe pain at the pit of the stomach immediately under the old scar. She was not jaundiced. She was confined on Jan. 15th and for the following six months her health was good. After that she began to suffer from attacks of vomiting and pain, with a feeling of fulness in the upper part of the abdomen, necessitating the loosening of her clothes about her waist. At first these attacks came on at intervals of about three months but gradually became more frequent until they occurred every week. After an attack she was always very tender in the centre of the upper part of the abdomen. For the last four weeks she has been continuously ill with pain in the epigastrium and vomiting and she also became jaundiced. Her temperature was 101° F. and at times slightly higher. She was extremely tender in the epigastrium, especially in the mid-line, so tender that it would have been quite impossible to define any tumour there unless it had been large. The abdomen was normal in appearance; the liver dulness was not increased and no enlargement (as of a hydatid) could be seen or felt. On the occasion of the first operation the cause of the jaundice was not at all clear. The hydatid was in the left lobe of the liver but it was very large and extended to the right side and so might have caused the jaundice by pressure, but this was very unlikely. There was no evidence of the cyst having leaked into the bile passages and so causing obstruction by the lodgment of a piece of membrane as occasionally happens. Dr. Moore was unable on account of the size and situation of the hydatid to examine the gall-bladder and ducts for calculi. There was no evidence of the existence of another hydatid. A gall-stone in the common duct seemed to be the most likely cause of the present pain and jaundice. It was decided to open the abdomen again.

Operation was performed on March 12th. Dr. Boyd gave the anæsthetic and Dr. Aitchison assisted as in the former operation. The abdomen was opened through the old scar by an incision from the tip of the ensiform cartilage to the umbilicus. The peritoneal cavity was easily entered as, contrary to expectations, there was only one small adherent band connecting the scar with the old hydatid, although the cyst had been drained for many weeks less than two years before. The white scar of the old hydatid was seen at the edge of the left lobe near the fissure. Lying just above the stomach a hard tumour stretching across the abdomen was felt at once. The cavity of the lesser omentum was opened and the tumour was carefully examined. It was obviously the pancreas which was enlarged throughout its whole extent and was uniformly hard and nodular; its head could be felt below the duodenum with an edge like the hard edge of a cirrhosed liver. A puncture was made near the head of the pancreas but nothing was found and there was no bleeding from the puncture. The gall-bladder and the bile-ducts were easily examined and no stone could be felt, neither could a stone be found at the orifice of the duct. The gall-bladder was considerably enlarged but was not tensely filled. A trocar was introduced into it and some thick greenish fluid withdrawn. The wall of the gall-bladder was thickened; its cut edge was almost too thick to permit of the use of the small Murphy's button which was now used to connect the gall-bladder with the hepatic flexure of the colon. A strip of iodoform gauze was placed near the communication between the gall-bladder and the bowel. The incision was closed with nine sutures of silver wire through the whole thickness of the abdominal wall and nine superficial horsehair sutures. The patient made an uninterrupted recovery. A portion of the gauze drain was removed on May 15th, another portion on the 17th, and the last piece on the 20th. A very little blood-stained serum came away along the drain. The sutures were removed on May 26th and the patient was allowed up on the 27th and went home on the 31st. The button was passed on the 26th. The jaundice lessened gradually from the time of the operation and within a fortnight had completely disappeared. There was no tenderness in the epigastrium; the patient expressed herself as feeling very well and she certainly looked well.

Remarks by Dr. MOORE.—The recovery of the patient was so rapid and so complete that one is inclined to doubt whether it could have been due entirely to the operation. Still her illness had been very persistent and was showing no signs of abatement. There can be little doubt but that the operation of cholecystenterostomy (draining the gall-bladder into the intestine) is to be preferred to that of cholecystostomy (draining the gall-bladder on to the surface).

Reviews and Notices of Books.

A Text-book of Physiology. By ISAAC OTT, A.M., M.D., Professor of Physiology in the [illegible] of Philadelphia. With 137 [illegible] F. A. Davis Company. 1904. Royal 8vo, pp. 563. Price $3 net.

THIS text-book is intended to furnish the students attending Dr. Ott's lectures delivered in the Medico-Chirurgical College of Philadelphia with an epitome of the subject of physiology. The size of the work precludes much originality in the treatment of this far-reaching branch of medical knowledge, for it is not possible in the compass of 600 pages to give more than the barest outline of even such fundamental divisions of physiology as the circulation, respiration, and digestion. The author has still further restricted the space at his disposal by introducing much histological detail which in this country is usually taught in a practical manner. This naturally leads to the omission of many facts with which the student should be familiar and which we presume are taught in the laboratory of the college; the senses of hearing and of vision together only occupy 33 pages and many of these are taken up with the anatomy of the internal ear and with the structure of the retina, the illustration accompanying the text in the latter instance being the obsolete one of Landois. Stereoscopic vision is not explained, though there is a diagram illustrating binocular vision. The best chapters are those devoted to the subjects of digestion (in which are embodied the results of Pawlow's experiments), the circulation, and animal heat, in which last section the author describes a useful calorimeter which he has devised and which is appropriate for experiments both on animals and on man. With this instrument he finds that of the entire amount of heat dissipated about 14 per cent. is thrown off from the lungs, an estimate that is probably correct. Dr. Ott was the first to demonstrate the presence of thermogenic centres in the corpora striata and in the optic thalami which act through the trophic centres in the anterior cornua. In support of this view he points out that intravenous injections of putrid blood and of a substance named β-tetrahydro-naphthalamin are followed by a great rise of temperature due to excitation of the thermogenic centres. If, however, a section be made behind the tuber cinereum no rise of temperature is to be observed. The lettering of the diagrams requires attention; for example, in Fig. 100, which represents a transverse section of the spinal cord, there are two "T. G.'s," one for Goll's tract and the other for Gowers's. The author does not always express himself correctly; for example, in speaking of the muscular structure of the heart he observes, "the muscular fibres of the auricles consist of two kinds," the context showing that he means that the fibres are arranged in two sets or run in two directions; and again, in discussing the functions of the fifth and seventh nerves, he states that "while the trigeminus is responsible for the sensory actions of the face the facial presides over the contraction of the facial muscles of expression." "The sensory actions of the face" is not, we submit, a happy term. The text-book, when supplemented with the observations and experiments of the lecturer, will doubtless supply the students of the Philadelphian College with sufficient physiological knowledge to enable them to understand the principles on which the practice of medicine is founded but in the future editions through which we trust the work may run we think that it might be expanded with advantage to include some parts of physiology which are very curtly treated or the author might leave the histological details to the anatomist and thus obtain more space for pure physiology.

Lyon's Medical Jurisprudence for India. Third edition. Revised by Lieutenant-Colonel L. A. WADDELL, I.M.S. Calcutta, Bombay, and London: Thacker, Spink, and Co. 1904. Pp. 704. Price R.18.

THE medical officer in India in search of guidance in matters connected with medical jurisprudence cannot complain to-day of any absence of authority on this subject, for he has been fully equipped with the great work of Gibbons, a work by Collis Barry of Bombay, and now the third edition of the well-known work of Brigade-Surgeon I. B. Lyon, C.I.E., I.M.S., has appeared. The author has been fortunate enough to secure the coöperation of Lieutenant-Colonel L. A. Waddell, C.I.E., I.M.S., an officer fully qualified for the task, inasmuch as he has been professor of chemistry, Medical College, Calcutta; chemical examiner to the Governments of Bengal and India; and examiner in medical Jurisprudence, University of Calcutta. This edition will be found on examination to merit fully the favourable review which it received on its first appearance.

The work opens with an introductory chapter on Medical Relations with the Law Courts. This section contains pretty nearly all that a medical witness need know and most useful hints for giving evidence are detailed. The difficulties of detecting crime in India medico-legally are pointed out, such as the rapid decomposition of the body, the facilities for concealing dead bodies or so disposing of them that they may escape discovery, the false evidence fabricated by the police, and false confession of fictitious murder. We next come to the subject of identification of the living and the dead. Here again peculiar difficulties occur in India, due to the heat or perhaps to the ravages of beasts and birds of prey. The data for estimating the age of the living are gathered from examination of the teeth, height and weight, and some minor signs, together with the extent of ossification. We may draw attention to a simple rule propounded by Major W. J. Buchanan, I.M.S., as the result of 28,000 observations on healthy adult prisoners—namely, taking five feet as equal to 100 pounds, three pounds in weight are added for every full inch above that—e.g., 5 feet 6 inches $= 100 + 3 \times 6 = 118$ pounds. The caste and conventional markings are clearly contrasted as they exist amongst Hindoos and Mahomedans. Lieutenant-Colonel H. H. R. Charles's researches into the differences between Oriental and European skeletons are detailed and the importance of a knowledge of them is manifest in the case of an inquiry as to the disappearance of a British soldier from cantonments when a skeleton is brought forward as that of the missing man. The section which is devoted to the examination of the dead enters fully into the signs of death; the time of onset of cadaveric changes is shown to occur, as was to be expected, considerably earlier in India than in Europe. The points especially to be noted in post-mortem examinations are given and a useful table of the weights of the various organs of adults of Bengal and Bihar is given. The author then passes on to the discussion of stains caused by blood and semen. Uhlenhuth's test for the discrimination of human blood is described; it is a specific test of great delicacy and has been found applicable to stains which had been dry for three months.

Part II. of the work discusses injuries by violence other than sexual, wounds, asphyxial deaths, burns and scalds, heat stroke, starvation, and sexual crimes and offences. The subject of unnatural sexual offences is one of the most frequent that is brought before the civil surgeon in India; unfortunately, there are no signs that can be said to be always present as indicating whether such an offence has been committed or not. A case is mentioned which gave not the slightest indication after 20 years' practice of the offence. Pregnancy in relation to crime and illegitimacy is the next subject treated of; then follow sections on matters pertaining to legitimacy and inheritance. The subject of fœticide is next dealt with; criminal abortion is undoubtedly very prevalent in India, being resorted to in order to get rid of the product of illicit intercourse or to avoid inconvenient additions to families. Hence this subject is one demanding full recognition. The various means by which abortion is produced are discussed and instances are given illustrating them. In the chapter on infanticide, a crime which is very frequent in India, the author considers the matters relating to the examination of the child, its degree of maturity, whether it lived after its birth, and the cause of the child's death. He finally details the facts concerning the examination of the alleged mother.

Lunacy in India is relatively infrequent in occurrence compared with its incidence in Europe. Thus the census of 1891 revealed a proportion only of 5 per 10,000, as against 33 per 10,000 of the population in England. The subject is considered under its various heads and the legal aspects are fully entered into. A very useful section is devoted to the diagnosis of feigned insanity. A chapter next follows on life assurance. The remaining portion of the treatise is occupied with the subject of poisoning. This section, comprising about two-fifths of the work, deals with the whole subject most exhaustively, nor is too large a portion devoted to it considering that in Bengal murder by poison occurs from three to four times more frequently than in England. Arsenic and opium are the two poisons most frequently chosen for taking human life in India and the reader will find both of them fully discussed. A series of appendices concludes the book and contains directions with regard to various medico-legal circumstances in which the Indian practitioner may want advice. The work, we may say in conclusion, forms a trustworthy guide to the subjects of which it treats.

Alcohol: its Place and Power in Legislation. By ROBINSON SOUTTAR, M.A., D.C.L. London: Hodder and Stoughton. 1904. Pp. 259. Price 3*s.* 6*d.*

THIS survey of the liquor question is based upon a dissertation which the author presented to the Faculty of Law at the University of Oxford when he was qualifying for the degree of D.C.L. Certain chapters of a non-legal character have been added and the law of licensing in Scotland has been brought up to date. The book is dedicated to the magistrates who in the matter of licensing have been constituted trustees for the common weal in the hope that a survey of matters relating to the liquor question, written in moderate

THE LANCET.

LONDON: SATURDAY, JULY 2, 1904.

Immunisation against Infection of Operation Wounds.

IN the never-ceasing warfare waged against the attacks of micro-organisms the weapons of war are many. Some of them are afforded by the body itself, for it is no passive spectator of the battle but a very valuable combatant. Indeed the exertions of the physician are chiefly directed to modifying or increasing its spontaneous efforts rather than to the addition of entirely new modes of fighting infection. The most obvious method of destroying organisms, the employment of ordinary chemical antiseptics, is only to a very slight extent available, for the microbes are in contact with the living tissues of the body and a substance capable of destroying the parasite will be only too likely to destroy the sheltering host. To a small extent, however, antiseptics can be used when they are specially antagonistic to some individual organism and it is not unlikely that the action of quinine in malaria is mainly at least to be attributed to its bactericidal action on the plasmodium. There are, however, other weapons, less obvious perhaps but more effective, which we are able now to wield with no small effect in certain cases of disease. The resisting power of the living body is no invention of the imagination. Against the human body, for instance, the attacks of many micro-organisms, fatal to some of the lower animals, are in vain. It is certain, too, that even when the body is not absolutely immune to an organism it can resist to some extent its onslaughts and this resisting power varies from day to day. Under some conditions it increases and under others it diminishes. For many years this resisting power has been recognised but it is only comparatively recently that it has been possible to measure it accurately and to gauge the effect of treatment on it. Still more recently have means been discovered by which we can to some degree at least increase or diminish this resistance of the body and it is in this power of modifying the defensive strength of the living body that, so far as we can see at present, the great hope of the future rests. On what does this immunity depend? There are several methods by which a body resists or controls the incursion of micro-organisms. Perhaps the most striking is phagocytosis, the process by which the white corpuscles, acting as the living amœbæ which they so closely resemble, envelop and destroy by digesting many microbes. This action of the leucocytes is certainly of importance but it is probable that METCHNIKOFF over-estimated its relative value, for the white corpuscles have still another mode of destroying bacteria which is of even greater effect. The leucocytes elaborate chemical substances which inhibit and destroy bacteria and the main resisting power of the body is probably attributable to this property. The alexins, as these chemical substances have been called, are especially prevalent where there is leucocytosis. After a pathogenic microbe has invaded the body still another antagonist tends to develop. Special antitoxins are formed which are antagonistic merely to the organism which has given rise to them. To the formation of antitoxins acquired immunity is due. Some of these means of combating bacteria are utilisable in disease but the surgeon has not been able to avail himself of their assistance to any great extent. Lately some progress has been made in this direction and a lecture by Professor MIKULICZ, delivered before the West London Medico-Chirurgical Society and published at p. 1 of our present issue, describes the present position of our knowledge of the subject, especially in relation to operation wounds.

During and after operations the danger of microbic infection is chiefly guarded against by strict attention to those methods and precautions which are associated with the name of LISTER. In some operations, however, as in those involving the stomach and intestines, the risk of infection of the peritoneum is exceptionally great and therefore surgeons would be glad if some additional aid could be afforded to them. It is clear, too, that it would be better if this protection could be given prophylactically rather than therapeutically, for peritoneal infection is very much more controllable at the outset than when it has widely developed. Specific immunisation is hardly practicable, for the variety of micro-organisms which may affect the peritoneum is very great, and therefore we must fall back on some other method. The double power of the leucocytes in phagocytosis and in the preparation of alexins suggests that if we can produce a general or even a local increase in the number of white corpuscles (or hyper-leucocytosis) we shall be able to repel the septic invasion. Professor MIKULICZ'S lecture dealt mainly with the various means which have been adopted in endeavouring to cause a hyper-leucocytosis and their success. It has been found that the injection of various substances into the bodies of animals, both subcutaneously and intraperitoneally, leads to a hyper-leucocytosis some seven hours later. The substances chiefly employed have been albumose, saline solution, and nucleic acid. This mode of producing hyper-leucocytosis is not likely to be of much value in treating disease which has already developed, for the body at the time of the application of the remedy is overpowered by the toxins of the invading microbes; it cannot respond to the stimulus of the injected material and a still further artificial hyper-leucocytosis is impossible. It is an entirely different question, however, whether this method cannot be employed prophylactically and much work has been done in this direction. An animal is injected with one of the immunising substances and then a few hours later, when the hyper-leucocytosis has developed, the peritoneum is infected with a culture of bacterium coli. It is found that the injection of the substances already mentioned can increase the resisting power so that in some cases 30 or 40 times the lethal dose of the bacterium coli may be injected harmlessly.

Nucleic acid seems to be the most powerful of these immunising substances and repeated injections are needed to produce the best effect. How far are these results applicable to man? The solution of nucleic acid which appears to be most useful is of the strength of 2 per cent. and one gramme per 75 kilogrammes of body weight was used in all cases. In man, as in the animals employed experimentally, a hyper-leucocytosis always appears to be preceded by a temporary decrease in the number of leucocytes. In man the maximum of hyper-leucocytosis occurs later than in animals and therefore Professor MIKULICZ gives the prophylactic injection 12 hours before the operation. No harmful manifestations follow the injection though there is a slight rise in temperature. As to the results, Professor MIKULICZ is of opinion that the cases treated in this way have given more favourable results than those obtained previously, not only in the proportion of cases which recovered but also in the progress of the individual cases. Of 45 laparotomies in which the abdominal cavity was exposed to infection of the contents of the stomach or the intestines or by some other infective secretion 38 recovered and in none of the seven fatal cases was peritonitis the cause of death. A valuable adjuvant to the subcutaneous injection of nucleic acid appears to be the flushing of the peritoneum with saline solution. While it is yet early to pronounce definitely on the value of this prophylactic hyper-leucocytosis we have facts enough before us to declare that the outlook of the process is exceedingly hopeful. We are justified in expecting that the developments which the future will reveal will enable us to guard against risks of septic infection even in cases where those risks now appear to be greatest.

The Site of St. George's Hospital.

A SPECIAL court of the governors of St. George's Hospital was held on June 21st at the Westminster Palace Hotel, as we reported in our columns last week, to receive the report of the committee appointed more than a year ago to consider the desirability of removing the hospital to another site. From the brief account of this meeting which we have given it will be seen that the report of the committee was on the whole not in favour of removal, although there was incorporated within it the report of a subcommittee which was mainly on the side of removal, while a minority report strongly signed also took this latter view. By the publication of these reports the public has become aware of the arguments relied upon by each side in a most interesting and important controversy. The site of St. George's Hospital is one of the grand sites of the world. There may be small spots in overcrowded business centres in the City of London and in the business end of New York city, for example, where ground is worth more per foot, but with the exception of such spots there are probably few pieces of land in the world more pecuniarily valuable than that occupied by St. George's Hospital. A position which commands the entrance to the Royal Palace in the capital of the Empire, which marks the commencement of the most fashionable thoroughfare in that capital, and which fronts the main ingress to its greatest pleasure park, has claims to value paramount to any save the most artificial commercial conditions. It leaps to the eye that such a site is worth a very large sum of money; it is estimated, indeed, to be worth from £12,000 to £15,000 per annum as ground rents. Consequently the popular view is that to maintain a hospital upon such a site is a reckless piece of extravagance, while the idea of building a new charitable institution in the same spot suggests lunacy.

Why not, say many people—and it is the most obvious thing to say—sell this extraordinarily valuable land and with the proceeds buy land in a cheaper market, build a brand new hospital and medical school, and pay the surplus of the purchase money to the credit of the charity? Against this view we have, first, the fact, perfectly well known but apparently ignored, that the whole of the ground on which the hospital stands does not belong to the hospital, so that the sale of the site is complicated by a dual ownership. The inconvenience of this is proved by the fact that although it has been an open secret for so long that a large money offer might be entertained no purchaser has come forward willing to give a price commensurate with the estimated value of the land. Secondly, the estimated price, something between £300,000 and £400,000, when looked carefully into, does not prove to be a superabundant sum for the purchase of land more or less in the neighbourhood of Hyde Park Corner and the erection thereon of a modern hospital and medical school. As for there being any surplus for an endowment it is difficult to see how anyone can be so sanguine as to hold the view. If a hospital is to be built upon the spacious lines that would insure it freedom from all criticism for, say, 50 years, and if it is to have connected with it a completely modern medical school fit for all present demands and fit also to be adapted to all demands that can be foreseen in the future—if all this, then the purchase price of the present site would barely suffice for the immediate needs of the new building. That is to say, that so far as the charity is concerned nothing in capital would be gained by the revolution. And the public also would gain nothing that can be ascertained for certain. As the hospital stands at present it occupies a place of extreme convenience to the public. It is accessible and in the immediate neighbourhood of the constant scene of accidents of all kinds. It serves a large poor population who do not live very far from its portals, and the police will testify to its inestimable value as a station for the treatment of emergencies. These considerations prevailed with the meeting which passed by a substantial majority a motion—

"That it is not desirable at the present time and under existing circumstances to move St. George's Hospital from its present site."

Mr. C. G. HEATHCOTE, the governor who proposed this motion and who was a member of the committee which had reported on the whole question, strengthened his case by a judicious speech, pointing out that the hospital would not obtain the great benefactions which it had received from the public in the past if it were placed in Chelsea or Fulham; that they would be giving up a position unequalled in any large town in the world for healthiness, convenience, and access without any certainty of obtaining compensating advantages. He also reminded the meeting that the hospital as it stands is not an ancient insanitary barrack but a thoroughly well-equipped and efficient place for dealing with disease. This is another point that seems to have escaped the critics of the policy of the governors of St. George's Hospital. There is no need for immediate and enormous building operations. There is much that should be done, and in all probability an early start will be made upon the buildings designed to occupy the site recently purchased from the Duke of Westminster immediately to the west of the existing structure, but until such a time as it is convenient to start rebuilding the present hospital can carry on its work adequately. Mr. R. H. C. Harrison, another governor who had also been upon the committee and who was one of the signatories of the minority report, fairly, even with moderation, advanced the view that the hospital ought to be moved to a less expensive site because, as trustees of a charity supported by voluntary contributions, the governors were not justified in remaining upon or rebuilding the hospital upon such valuable ground. His argument, as we have seen, in spite of its apparent force, is damaged by the actual facts of the case. The meeting saw this and voted in favour of not exchanging the substance for the shadow. The good of moving is problematical, the benefits to the charity and the public of remaining at "the corner" with which the hospital has been historically associated for so long are incontestable. The vote of the governors pledges them to use every endeavour to erect and to maintain upon their beautiful site a building adequate for the continuance of the splendid public services of the charity.

* * *

The Introduction of Beri-beri into South Africa.

During last week public attention was aroused by the report that beri-beri had been introduced into South Africa and the matter received attention in both Houses of Parliament but without any light being thrown upon the subject. Further questions have been addressed to the Colonial Secretary this week but they found him for a long time without anything to say. No official information was received until Wednesday last confirming the report from private sources that a tropical disease new to the locality had broken out among the imported coolies It would be supposed that the knowledge that such an event had taken place would be enough to justify the reception of the intelligence with gravity in Parliament but when Dr. C. F. Hutchinson, the Member for Rye, who was the first to ask for information upon the subject, referred to beri-beri as a disease of an intensely infectious and dangerous character, the Colonial Secretary replied, as though dismissing the matter, that he had every confidence that the methods used for dealing with the importation of plague would be employed with success. Dr. Hutchinson called this answer unsatisfactory, as indeed it was, but his repeated statement that the matter was of urgent importance was received with laughter by many Members of the House, while the Deputy-Speaker ruled that the subject could not be discussed as it was already covered by resolutions of which notice had been given. The Marquis of Ripon then called attention to the matter in the House of Lords, as it appeared that the House of Commons was not in a position to debate the subject, when he elicited from the Foreign Secretary that in answer to a telegram sent by the Government to South Africa no official information had been received. Since then Mr. Lyttelton stated that he had sent three telegrams and had obtained no response. At last, however, Lord Milner replied and we now know that one transport ship bearing coolies arrived at Durban with 40 cases of beri-beri on board and that 25 cases have occurred on the Rand. The broad question of the importation of Chinese labour into South Africa is one on which we are not called upon to speak, but quite apart from all matters of political morality and commercial expediency is the enormously important consideration that the introduction of the Chinese coolie into the South African mines may lead to the establishment in our African colonies of loathsome pestilences. This apprehension has been felt by many medical men and expressed by some and the attitude of the House of Commons upon the matter cannot have much impressed our profession with the wisdom or the business methods of that assembly.

The real measure of the danger of beri-beri must not be exaggerated and when Dr. Hutchinson described the disease in the House of Commons as of an intensely infectious and dangerous character he would probably, had he been permitted, have qualified his words by expanding them. A great number of views have been held as to the causation of beri-beri, some of which evidently have no foundation in fact, and from the obscurity with which the subject has been thus surrounded there has arisen a too gloomy pathological view. Thus the late Dr. Kynsey considered that one form of the disease was due to the presence of ankylostoma and possibly of trichocephalus dispar, while Pekelharing, Winkler, and others claim to have discovered a special beri-beri bacterium. These things require substantiation. Two theories which would certainly seem to explain the phenomena of the disease are that connected with diet and that connected with locality. With regard to diet, food deficient in nitrogenous elements or fatty elements would seem to be responsible in some cases for beri-beri. Thus formerly the disease raged in the Japanese navy. In 1882 from 30 to 40 per cent. of the sickness in the service was due to this disease and the diet was exclusively rice In 1884 an improved dietary was introduced when the mortality from this affection fell to 137 per 1000. In 1885 a still greater improvement was effected and the death-rate then became only 6 per 1000. As to the causation by rice it was found with regard to the Javan prisons that in those in which white rice was eaten 36 gaols out of 51 were affected, whereas amongst those in which red uncleaned rice was consumed only one out of 37 gaols was attacked, the untreated seeds being richer in nitrogenous properties. Deficiency in fat has also been held to be a cause of beri-beri. At Ponto-Condor an epidemic suddenly ceased on a regimen of fat pork being given. This theory is attributed to Brémand and there is not much to support it. Sir Patrick Manson holds the affection to be a disease of locality. This view received striking confirmation from an epidemic reported on by Mr. E. A. O. Travers at the Pudoh gaol, Selangor. The gaol was occupied in January, 1895, previously to which all prisoners were confined in the old distant. Whilst in the latter none of the prisoners contracted the disease, although feeding on the same rice from the same source as that given them when in the new Pudoh gaol; but the outbreak occurred immediately after a change of location of the prisoners, the supply of rice remaining the same. The mortality being so high in this new goal, the prisoners affected were transferred to the old gaol in October, 1895, in the hope that the change of residence might prove beneficial. That this was so is shown by the following statistics. In September the percentage of deaths was 31·7; in October on the transfer it sank to 15·57; in November to 6·15; and in December to 4·25. The food was exactly the same in both gaols, in fact that for the old gaol was actually cooked in the Pudoh gaol. Again there were three other large institutions in Kuala Lampur, all within three miles of the Pudoh gaol; the rice supplied to them was the same as that supplied to the Pudoh gaol; yet throughout the six years during which the disease was endemic in the Pudoh gaol no outbreak of beri-beri occurred in these three institutions. There are, in fact, good grounds for supposing that an epidemic can be cut short by changing the locality of the patients and by improving the dietary.

From this it appears that the general danger to the health of the South African colonies from the accidental introduction of beri-beri into their midst is not very great but it seems to us an extraordinarily unfortunate matter that the Government should not have been prepared to treat Dr. HUTCHINSON'S original question seriously. We cannot believe that the rules of the House would have really prevented the matter receiving attention had the Government not desired to avoid the discussion of an awkward matter. The Government ought to have taken proper steps to obtain information, for surely there is an urgent form of telegraphic question that commands attention. And they ought not to allow the Colonial Secretary to say or to suggest that "it would probably be all right about beri-beri because they had done so well about plague"—which is a perfectly fair paraphrase of Mr. LYTTELTON'S original reply. Such questions as the importation of new diseases into our colonies should be discussed in a different spirit. If a debate had ensued upon Dr. HUTCHINSON'S question it would have been elicited that no fear of a general spread of beri-beri in South Africa need be entertained. By laughter, and by the appearance of shirking the matter, an impression has been created in the public mind of insecurity.

Annotations.

"Ne quid nimis"

THE PREVENTION OF PULMONARY TUBERCULOSIS.

THE continuous progress of the movement for the prevention of consumption and other forms of tuberculosis has recently been exemplified simultaneously in the north and the south of England. In another part of our present issue we describe the opening of the sanatorium at Heatherside in Surrey by the Prince and Princess of Wales on June 25th. Suitable cases from Brompton Hospital will here enjoy obtainable in the densely populated neighbourhood of the parent institution. Again, on June 29th the Society for the Prevention and Cure of Consumption in the County of Durham met in Sunderland and had under consideration the general committee's report on the work of the society since its formation in 1898. The sanatorium under the management of the society is at Horn Hall, Stanhope, and was opened in May, 1900. The report states that the experience of the last four years has proved that as good results can be obtained there by the open-air method as in the most landed health resorts in any country. In addition the society claims to have solved the difficult problem of bringing sanatorium treatment for themselves and their families within the reach of men belonging to bodies of workmen who make small regular contributions (threepence per quarter per man). These payments provide free beds for the use of subscribing workmen and the members of their families dependent on them to the full extent of the total subscriptions. Patients who do not belong to bodies of subscribing workmen, and can pay either the whole or a part of their maintenance, are charged two guineas a week, several local authorities subscribe for the purpose of being enabled to send patients from their districts, and subscriptions are of course collected from the public for the support of free patients. Among the special measures for the prevention of the disease adopted in various parts of the county of Durham it is stated (1) that in every district except the borough of South Shields suspected sputum is examined for tubercle bacilli free of charge on application to the health authorities; (2) that voluntary notification of cases of consumption is in force in the boroughs of Sunderland, Gateshead, and Jarrow; and (3) that many local authorities offer free disinfection of rooms vacated by consumptives. The society strongly urges the establishment of homes for advanced cases in the interest not only of the patients themselves but also of the public at large. The sanatorium has 30 beds and during the year 1902–03 applications were received from 210 patients, of whom only 108 could be admitted. The average stay of each patient was 14·5 weeks and the average gain in weight was 18·3 pounds. About half of them had tubercle of both lungs and many suffered also from laryngeal affections and heart disease. On admission 59 had consolidation only of the lungs and were classed as early cases. Of these, 16 (or 27 per cent) were sent out apparently cured, 40 (or 66 per cent.) were very much improved, and three were improved but unsuitable for further treatment. In 39 patients signs of advanced disease with loss of lung tissue were present on admission. These were classed as "cavity" cases; 26 of them left the sanatorium very much improved, seven were improved, and six were unsuitable for further treatment The records for the four years during which the institution has been open show that out of 146 early cases discharged 99 are still at work, 22 are at home, three have been readmitted, and 25 are dead; out of 122 advanced or "cavity" cases 35 are still at work, 31 are at home, two have been readmitted, and 56 are dead These results show the extreme importance of commencing treatment in the earliest possible stage as soon as the disease is recognisable and are decidedly encouraging so far as they go, but sanatoriums ought to have, and no doubt in time will have, a merit greatly in excess of their utility as curative institutions We refer to the immense power which they may exercise in educating the public to appreciate the advantages of ventilation, fresh air, and attention to a few simple rules of individual hygiene. When we consider that many hundreds of anxious sufferers travel far from their homes and pass the whole day reclining in open-air shelters it is impossible to avoid picturing to the mind how much these unfortunates would have been the gainers both in health and purse if they had in their youth acquired the habit of disregarding "draughts" and always admitting plenty of fresh air to their apartments.

A VISIT OF FRENCH MEDICAL MEN TO LONDON.

Sir William S. Church, Bart., K.C.B., President of the Royal College of Physicians of London, occupied the chair at the College, Pall Mall East, London, S.W., on June 23rd on the occasion of a meeting of representative members of the profession in order to consider the arrangements which should be made to receive a party of French physicians and surgeons who propose to visit London on Oct. 10th, 11th, and 12th. On the motion of Dr. Frederick T. Roberts, seconded by Mr. Thomas Wakley, Jun., an executive committee, with Sir William Broadbent, Bart., as chairman, containing representatives of the principal hospitals and laboratories in London which the French visitors might wish to see was appointed. Sir Thomas Barlow, Bart., and Dr. J. Dundas Grant were elected treasurers, the secretarial work being entrusted to Dr. Dawson Williams and Dr. W. Jobson Horne. A guarantee fund was formed and subscriptions were promised by those present.

PARKES MEMORIAL PRIZE.

THIS prize, (which is given triennially and consists of 75 guineas and a bronze medal), has been awarded to Major R. Caldwell, R.A.M.C., for the best essay sent in upon "The Prevention of Disease amongst Armies engaged in Active Operations in the Field, with special Reference to the Sanitary Organisation of a Field Force." The essays submitted by Major E. C. Freeman and Major F. Smith, D.S.O., also of the Royal Army Medical Corps, were highly commended by the assessors. The subject of the next prize is "On the Sanitary Requirements of Naval and Military Units in Peace and War; with Suggestions for Complete Schemes of Sanitary Organisation suitable for both the Navy and the Army." The competition is open to officers of the navy, army, and Indian medical services. Essays should be submitted to the secretary of the Parkes Memorial Fund, Royal Army Medical College, Examination Hall, Victoria Embankment, London, W.C., on or before Dec. 31st, 1906.

CEREBRO-SPINAL MENINGITIS OF THE EPIDEMIC TYPE.

DURING the past four or five years much attention has been given to the study of cerebro-spinal meningitis in the United States where this disease is often prevalent in epidemic form, the researches of Councilmann who investigated the Boston epidemic of over 100 cases, and of Osler who investigated the Baltimore epidemic, having served to increase the interest and importance of the matter. In the *Medical News* of New York of June 4th Professor Henry Koplik has published an account of his studies on 77 cases of epidemic cerebro-spinal meningitis carried out by him during the last five years. 37 of these were bacteriologically examined and found to be undoubted cases, cultures of the meningococcus intracellularis of Weichselbaum being obtained from the patients in every case. 35 of the other cases were found to be due to the tubercle bacillus, one each to the pneumococcus, the staphylococcus, and the streptococcus, and two to the influenza bacillus. 15 other cases of the epidemic form were also studied by Professor Koplik and from a careful collation of the records of all these cases and from others in literature the following conclusions were drawn. As regards age infants and children are the most liable to be affected. Thus the oldest patient was only 14 years of age, 77 per cent. of the patients were under four years, and 60 per cent. were under two years of age. "My own cases," adds Professor Koplik, "are of the primary meningitic form and include at least one case of so-called posterior basic meningitis." The clinical types of the disease were the ordinary and well-known ones but a few "malignant" cases occurred which were fatal within from 24 to 36 hours. These malignant cases were marked by vomiting and subcutaneous hæmorrhages in the face, the hands, and the body. In young infants the onset of cerebro-spinal meningitis was sudden, with general convulsions, high fever, and vomiting, the fever being of the intermittent or remittent type and lasting over four weeks. Rigidity of the neck, general muscular irritability, and incipient wasting began within a few days or a week of the onset. Babinski's reflex was found to be present in 77 per cent. of the cases of tuberculous meningitis, its constancy in this affection being attributed to a probable degeneration of the pyramidal tract fibres descending from the affected Rolandic area of the brain. Kernig's sign was difficult to elicit in children below the age of two years but all children above the age of two years who suffered from cerebro-spinal meningitis exhibited this sign. Hyperæsthesia of the skin and mental irritability were observed in all cases in recent epidemics but were not so universal in previous epidemics. The blood invariably exhibited leucocytic changes. The leucocytes were of the polynuclear type in every case and varied from 20,000 to 50,000 per cubic millimetre, the lowest count being (in one case) 12,000. The cerebro-spinal fluid drawn off by lumbar puncture showed in nine out of 13 cases a predominance of leucocytes, while four showed the normal proportion. The most frequent complications of the epidemic forms of the disease were *otitis media*, *herpes labialis*, and *purpura*. Treatment consisted of lumbar puncture "which was especially indicated in vigorous patients," the puncture being repeated after five days if symptoms recurred after (temporary) relief. From 30 to 40 cubic centimetres of fluid were as a rule withdrawn at the operation but in exceptional cases where there was much tension double the quantity was withdrawn. Hot baths were found useful for allaying rigors, sponging was employed to lower the pyrexia, while calomel and the alkaline iodides in full doses were also serviceable.

PROVIDENT MEDICAL DISPENSARIES.

AN interesting letter was read at the annual meeting of the Metropolitan Provident Medical Association held on June 28th at 67, Eaton-square, London, S.W., in which Sir William Broadbent, after regretting his inability to attend the meeting, stated that he had for many years past given close attention to the work of the Metropolitan Provident Medical Association in providing good medical treatment for the working classes, including attendance at home. In his opinion the establishment of provident dispensaries afforded the true solution of the difficulties attending the securing of good and efficient medical advice for the self-respecting working classes. According to the annual report of the association, which was adopted by the meeting, at the end of 1903 there were 12,861 cards of membership—family and single—representing about 30,000 persons. The payments made by these provident members in small regular fees amounted to £5836. In his letter Sir William Broadbent observed that the club system of providing medical treatment by way of insurance was open to serious abuse on both sides and he considered that it would be a very good thing if the great benefit societies could affiliate themselves with the Provident Medical Association. One of the objects of the Provident Medical Association is to relieve the overcrowded hospital out-patient departments by a system of coöperation and on that point the opinion of

Sir William Broadbent, as expressed in his letter, was that as regards the working classes in hospitals, while working men and their families ought to have a first claim on hospitals as in-patients where operations were required and in cases of very serious illness, he thought it was sad when they were compelled to attend out-patient departments with the waste of time which that involved and the association and contact with the filthy and vicious people who so often crowded the waiting rooms. One of the important features of the association is coöperation with the medical profession generally, and on that point Sir William Broadbent wrote that there ought to be an organic connexion between the provident dispensary of any locality and the neighbouring hospital by which a member of the dispensary should be entitled to prior consideration at the hospital. In the latter part of his communication Sir William Broadbent affirmed that he was quite sure that the physicians and surgeons would agree to this and he believed that most of them would be ready to see provident dispensary patients at home in consultation with the medical officer in attendance at reduced fees. A motion was unanimously passed at the meeting to establish more provident dispensaries and all the speakers seemed anxious to let everyone know that the methods of the Metropolitan Provident Medical Association did not tend to pauperise the population.

THE BIRTHDAY HONOURS.

THE list of birthday honours does not include the names of any large number of medical men or of men prominent in the scientific world. Professor James Dewar receives recognition for his important work with regard to the liquefaction and consolidation of air and hydrogen by obtaining a knighthood. Three medical men have been knighted—Dr. T. Stevenson, Dr. C. Holman, and Dr. Kendal Franks, C.B. Sir Thomas Stevenson, scientific analyst to the Home Office, became an M.D. of the University of London in 1864, and in addition to his Government appointment at the Home Office is a lecturer on medical jurisprudence at Guy's Hospital, examiner in forensic medicine at the University of Birmingham, and analyst to several counties and boroughs. His excellent contributions to the standard literature of forensic medicine and hygiene are known to all our readers. Every member of the medical profession will hail with hearty satisfaction the announcement that a knighthood has been conferred upon Dr. Holman who has worked so hard in connexion with the beneficent and educational work of Epsom College as treasurer and vice-president. Sir Constantine Holman, who received his medical education at Guy's Hospital and at the University of Edinburgh, was for many years in practice at Reigate and an outline of his professional career appeared recently in our columns on the occasion of the presentation to him by the medical profession of a testimonial. Sir Kendal Franks received his medical education at Dublin and at Leipsic. He is an M.D. of the University of Dublin and a Fellow and ex-vice-president of the Royal College of Surgeons in Ireland. He has held many important appointments and is at the present time Principal Medical Officer to H.M. Forces at Capetown. An interesting feature of the honours list this year is afforded by the decorations awarded in commemoration of the jubilee of the Crimean war. Among the recipients are Surgeon Thomas Ligertwood (retired pay), late physician and surgeon to the Royal Hospital, Chelsea, who is made a Companion of the Bath in the Military Division. He served at Alma, Inkerman, and Sebastopol. Among the new Knight Commanders of the same Order are Deputy Surgeon-General James Howard Thornton, I.M.S., C.B., and Surgeon-General Edmond Townsend, A.M.S., C.B., C.M.G., both of whom are promoted from the Companionship of the Bath. Surgeon-General William James Fawcett, A.M.S., has been made a Companion of the Bath in the Military Division, and Hon. Colonel John Edward Squire, lately commanding the Home District of the Royal Army Medical Corps (London Companies) Volunteers, a Companion of the Bath in the Civil Division. Mr. Bolton Glanvill Corney, M.R.C.S. Eng., Chief Medical Officer of the Colonial Government at Fiji, has been appointed a Companion of the Imperial Service Order. To each of the recipients of these honours we offer in the name of the medical profession hearty congratulations.

THE SANITARY INSTITUTE.

WE may remind our readers that the twenty-second congress of the Sanitary Institute will be held at Glasgow from July 25th to 30th under the presidency of the Right Hon. Lord Blythswood, Lord Lieutenant of Renfrewshire. The list of presidents of the various sections has already been published in our columns.[1] The arrangements which have been made for the convenience of intending visitors to the congress appear to be all that could be desired and we have received from the secretary (Mr. E. White Wallis) a number of documents, including the preliminary programme, setting forth the various papers that will be read at the congress, particulars of excursions and social functions, the method of obtaining cheap railway tickets to Glasgow and other places in connexion with the congress, and a list of hotels and apartments, giving the tariff, and so forth. Full particulars can be obtained from the Parkes Museum, Margaret-street, London, W., and from the local offices, City Chambers, Glasgow. Since the Sanitary Institute was formed in 1876 it has done much good work in educating the public in sanitary matters. The Parkes' Museum of Hygiene, which was instituted as a permanent memorial of Dr. Alexander Parkes, the first professor of hygiene at Netley, has also become a powerful auxiliary to the educational influence of the institute.

COLLIERY CONTRACT PRACTICE IN NORTHUMBERLAND.

PRIOR to the formation of the Northumberland and Newcastle Medical Association the medical officers to the miners in Northumberland were paid by the miners 6*d.* a fortnight per family for medical attendance, the payment being supplemented by small fees with regard to grown-up sons or lodgers. This rate of pay continued for 60 years until the association was formed, when a movement was started which proved successful to raise the fees to a minimum of 9*d.* per fortnight. The Miners' Association, we are informed, has now decided to take steps to bring about a reduction of 50 per cent. in these fees on the grounds that since the medical rates have been raised wages have fallen gravely. If the wages of the miners have fallen below a fair figure we are ready heartily to support any movement for raising them again, but the contention that the pay of the medical men should therefore be reduced is quite illogical. The pay of the medical men had to be raised (1) because the cost of medical education is double what it used to be when 6*d.* per fortnight per family was fixed as a fair figure; (2) because the medical curriculum is now five years instead of three years; (3) because unqualified assistants are no longer permitted by the General Medical Council to assist practitioners; and (4) because the modern appliances of medicine are very expensive to buy. These are the circumstances that make it impossible for medical men in justice to themselves to put up with the old standard of payment and we trust that no member of the medical profession will accept any appointment of any description in the county of Northumberland without first inquiring from

---

[1] THE LANCET, Feb. 13th, 1904, p. 451.

Mr. Garforth Drury, 95, Pilgrim-street, Newcastle-upon-Tyne, secretary of the Northumberland and Newcastle Medical Association, as to the circumstances of the appointment. Dr. A. Cox of Gateshead, secretary of the North of England branch of the British Medical Association, will also give information on the subject to intending applicants.

THE JAPANESE AS CHEMISTS.

PROBABLY no Eastern nation is more strongly represented than are the Japanese in the English annals of science and more particularly in literature on chemistry. They possess an undoubtedly strong faculty for original research and they combine this faculty with a sharp-sightedness as to the possibilities of practical application of the fruits of research. The Japanese chemist, in fact, unites the power of originality of the English chemist and the practical intuition of the German. At the University of Tokyo practical study is very much favoured and splendid facilities for work are provided in the laboratories and workshops. There are several distinguished Japanese chemists who are Fellows of the English Chemical Society and who were elected to the Fellowship on account of the excellence of their contributions to original science. Many elaborate papers involving long and patient laboratory investigation are printed in full in the Transactions of the society. The Japanese chemists discuss with a freedom which astonishes the Western chemist all the modern abstruse theories bearing upon the atomic theory, the constitution of matter, the theory of dissociation, and so forth. They write powerful dissertations on the views advanced by such esteemed thinkers as Ostwald, Arrhenius, Van 'tHoff, Kelvin, Thomson, Lodge, Crookes, Ramsay, and others and have offered valuable criticisms on the methods of systematising and compiling atomic weights adopted by Western chemists. Chemistry, of course, is a powerful weapon in war and there can be little doubt that amongst other things which have so far contributed to Japanese successes is a sound knowledge of explosives, their composition, action, and behaviour under a variety of conditions. When there is no longer any need for the implements of battle, and may that soon be, we may be pretty sure that the same subtle insight which is so marked a feature of the Japanese intellect will turn with equal success to the application of science to peaceful pursuits.

THE EPILEPTIC COLONY AT CHALFONT.

THE life of the epileptic is one of involuntary idleness while his existence in the community at large is a source of distress and danger to others. The epileptic farm-colony at Chalfont St. Peter, which has been in existence for ten years, provides for these sufferers a home where they can be taught under proper supervision to follow the avocations of ordinary life, to engage in industries of various kinds, and to take part in healthy outdoor games and amusements. The eleventh annual report of the colony, to which we alluded briefly last week, states that "several homes have already [lately] been opened ...... but the existing accommodation is nevertheless utterly inadequate to meet the demand for admission and funds are most urgently needed for the building of additional homes." Annual subscriptions or donations may either be given for the general purposes of the society or allocated to the building and extension fund or the maintenance fund. A contribution of £200 will reserve a bed for eligible patients nominated by the donor. A contribution of £4000 will provide and equip a home for 24 patients and will give priority of admission to a corresponding number of eligible candidates belonging to any county or other district in which the donor may be specially interested. A scheme had been prepared which if carried into effect would have resulted in the building by the London School Board of homes for epileptic children (under the jurisdiction of the London School Board) in contiguity to the Chalfont [illegible] of these homes to the National Society for Employment of Epileptics which administers the Chalfont colony, a fixed weekly sum being arranged to be paid for the maintenance of each child. The number of children that would eventually have come within the scheme was estimated to be about 150. The scheme was, however, subject to the sanction of the Board of Education and on the matter being referred to it by the London School Board the former, without in any way disapproving of the scheme, expressed the opinion that in view of the approaching transfer of the functions of the School Board to the London County Council the consideration of the matter ought to be postponed. The clauses in the Education Act (1899) which stood in the way of the colony accepting the care of these children being removed by a new measure promoted by the National Society, and passed in Parliament recently, this work is now possible. At the beginning of the year 1903 there were in residence at Chalfont 114 male and 56 female colonists. During the year 22 males and 22 females were admitted and 22 males and 21 females were discharged, leaving in residence at the end of the year a total of 171. Besides the regular colonists there were received during the year ten convalescent or temporary cases. The institution has been remarkably free from scarlet fever, diphtheria, and small-pox, though outbreaks of these diseases occurred in the immediate vicinity of the colony. Only a single case of scarlet fever occurred among the colonists and the patient was at once isolated and treated with satisfactory results. Anyone interested in promoting the welfare of epileptics and desirous of any information conducive to that purpose should communicate with the secretary of the National Society for Employment of Epileptics, 12, Buckingham-street, Strand, W.C., who will always be happy to give any information and assistance in his power.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ON Thursday next, July 7th, the counting of the votes for the election of three members of the Council of the Royal College of Surgeons of England will take place. By the regulations of the College six Fellows unconnected with the Council must be present. On several occasions much delay has occurred in consequence of the difficulty of making up this number; it is therefore hoped that any Fellows who can spare the time will attend at the College on Thursday at 2 P.M. so as to enable the counting of the votes to take place. Attendance is necessary for a few minutes only and as the additions to the museum will be on view the time required may be well spent.

THE COMMERCIAL PRODUCTION OF VACCINE MATERIAL.

IN an article on Vaccine and Vaccination published in the April number of the *Bulletin of the Johns Hopkins Hospital* Dr. George Dock of Ann Arbor, Michigan, when describing the systematic cultivation of vaccine material by inoculating calves, says that the "seed" vaccine used in the inoculations is of various kinds. Sometimes it is bovine virus selected with care from well-developed vesicles and of tested bacterial purity. Sometimes it is selected humanised vaccine lymph and sometimes it is material derived more or less remotely from human variola. Often the manufacturers either do not know or are unwilling to state the source and nature of the "seed" and misrepresentation has occasionally occurred. With regard to the quality of the product he remarks that commercial vaccine virus has an unnecessarily large bacterial contamination and these organisms though usually harmless may sometimes be pathogenic, as in the remarkable development of tetanus following vaccination in several parts of the United States in the end of 1901.[1] On the subject of the essential efficacy of the vaccine material produced by various manufacturers Dr. Dock says :—

[illegible]

improvement.

THE CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH AT FOLKESTONE.

THE Congress of the Royal Institute of Public Health will be held at Folkestone this year from July 21st to 26th under the presidency of the Right Hon. the Earl of Radnor. In the sections of Tropical Medicine and the Early Physical Training of the Navy, Army, and Imperial Forces, of which Dr. W. J. Simpson and General Sir William Stirling, K.C.B., are respectively the presidents, papers of particular interest at the present moment will be read and discussed by Mr. James Cantlie, Colonel A. Crombie, C.B., I.M.S. (retired), Brigade-Surgeon-Lieutenant-Colonel W. Hill-Climo, A.M.S. (retired), Surgeon-General G. J. H. Evatt, C.B., A.M.S. (retired), and Brigade-Surgeon-Lieutenant-Colonel James Turton, A.M.R. In the section of Comparative Pathology, Bacteriology, and Chemistry Dr. Edward E. Klein, F.R.S., is the president, the title of his address being "The Aim and Scope of Bacteriological Analyses of Water and Shell-fish with Reference to Sewage Pollution." In connexion with this congress we are in a position to state that an endeavour will be made to discuss fully the question of the Jones Sanatoriums in accordance with the suggestion of our Special Sanitary Commissioner in his articles on the Folkestone Public Health Congress and the Sandgate Scandal, the concluding one of which will be found at p. 47 of our present issue.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE sixty-third annual meeting of this association will be held on July 21st and 22nd at 11, Chandos-street, Cavendish-square, W., under the presidency of Dr. R. Percy Smith. At 9.30 A.M. on July 21st a council meeting will be held and at 11 A.M. officers of the association and members of council will be elected and other private business transacted. At 2 P.M. on the same day the President will deliver his address, after which Dr. G. E. Shuttleworth will read a paper on the Education and Treatment of Young Epileptics and Dr. C. Hubert Bond a paper on a Plea for the Closer Study of the Body Weight and its Relation to Mental Disease. On July 22nd at 10 A.M. papers will be read by Dr. A. W. Campbell and Dr. John Turner dealing respectively with Further Histological Studies in the Localisation of Cerebral Function and the Finer Anatomy of the Nervous System with Special Reference to the Doctrine of Continuity. The Psychology of Hallucinations is the title of a paper which will be read by Dr. W. H. B. Stoddart. [illegible] will be read by Dr. G. M. Robertson, Dr. J. Milson Rhodes, and Mr. J. Carswell at 2 P.M. On the evening of July 21st the annual dinner will be held at the Whitehall Rooms of the Hôtel Métropole, and on July 22nd, from 4 P.M. to 7 P.M., the President and Mrs. Percy Smith invite members of the association to a garden party at the Botanical Gardens, Regent's-park, N.W. Tickets for the dinner can be obtained from the honorary secretary, Dr. Robert Jones, price one guinea, including wine.

THE WEST LONDON HOSPITAL AND POST-GRADUATE COLLEGE.

THE annual dinner of the West London Hospital and Post-Graduate College was held at the Trocadéro Restaurant, Piccadilly-circus, on June 25th, Dr. J. Barry Ball occupying the chair. The dinner was well attended by the staff of the hospital and college and by post-graduate students. There were many guests, including Professor von Mikulicz of Breslau, Sir Felix Semon, Dr. F. de Havilland Hall, and Fleet-Surgeon G. Welch, R.N. During the evening various toasts were given and enthusiastically received, among them that of "The West London Hospital and the Post-Graduate College," which was responded to by the Dean, Mr. L. A. Bidwell, and that of "The Visitors," for whom Professor von Mikulicz replied. An exhibition of sleight of hand was given by Mr. Charles Bertram.

CHANGES IN THE INTERCOSTAL MUSCLES AND DIAPHRAGM IN INFECTIONS OF THE LUNG AND PLEURA.

IN the *American Journal of the Medical Sciences* for May Dr. W. M. L. Coplin has published an important paper on Changes in the Intercostal Muscles and Diaphragm in Infections of the Lung and Pleura—a subject which seems to have received little attention. Rosenbach speaks of atrophy of, and pains in, the thoracic muscles in pleurisy. Rohrer has shown that in pneumonia and pleurisy an interstitial myositis of the part of the diaphragm adjacent to the affected area occurs.[1] Dr. Coplin has studied the condition of the intercostal muscles in seven cases—two of croupous pneumonia with plastic pleurisy, two of tuberculosis of the pleura, two of pneumococcic pleurisy, and one of empyema. In the two cases of croupous pneumonia the diaphragm was also examined. Marked granular changes were found in the muscular fibres, apparently identical with the cloudy swelling which occurs in infectious diseases. Dr. Coplin therefore thinks that this change is only part of an alteration of the general musculature due to toxæmia. But there were also changes probably due to extension of the inflammation from the adjacent serosa. The muscle fibres were dissociated and separated by a granular acidophilic deposit (indicating œdema). Groups of fibres showed hyaline degeneration. What appeared to be a more advanced stage of the changes just described consisted in leucocytic infiltration of the muscle and necrosis of the fibre. In this stage pneumococci and other organisms were found in the muscles. Fibrin was abundantly present. Specimens showing a further stage and the ultimate result in cases of recovery could not be obtained. Evidence of suppuration was usually absent but no doubt small necrotic areas infiltrated with leucocytes were really microscopic abscesses. The general pathology of myositis points to the inference that with subsidence of the infection the necrotic muscular tissue would be removed by phagocytes and that some fibrosis would result. The following case is an example. A man, aged 22 years, had left-sided pleurisy of six years' duration which terminated in empyema. On June 9th, 1903, three quarts of pus were removed by aspiration. A week later two inches of the seventh rib were excised and the cavity was drained. The patient improved and left the hospital. He returned on Oct. 26th with the heart still displaced to the right and the left chest deficient in resonance and the respiratory sounds diminished in the upper half and absent in the lower. Professor Keen performed thoracic resection, removing the greatly thickened pleura with the chest wall from the third to the seventh rib inclusive. On Dec. 2nd there were signs of œdema of the lung and death occurred two days later. A necropsy was not obtained. Microscopic examination of sections of the soft parts removed showed in the majority only fibrous tissue most of which was in the early stages of formation though some of it was dense. There were also granulation tissue and muscle which had undergone considerable changes—atrophy, fatty degeneration, vacuolisation, and fragmentation. The clinical importance of such changes in the intercostal muscles is evident, for they may be a factor in the dyspnœa of diseases of the chest.

NORTH INDIA SCHOOL OF MEDICINE FOR NATIVE CHRISTIAN WOMEN.

WE have received from the secretary of the Medical Missionary Association, a pamphlet[1] descriptive of the North India School of Medicine for Native Christian Women at Ludhiana in the Punjab. The school was started nine years ago and at present has 35 students in training—19 as hospital assistants, six as dispensers, and ten as nurses; there are also ten midwives. In connexion with the school there are a dispensary and a hospital of 70 beds where everything is done to satisfy the ceremonial requirements of high-caste patients. As no man is allowed inside the hospital five small zenana or purdah homes of three rooms each have been built with access to the street so that the patients may see their husbands or male relatives without disturbing other purdah women who must never be seen by strange men. The school is governed by a committee in India which has upon it representatives of several different societies; there are also auxiliary home committees in London, Edinburgh, and Dublin. One of its great needs is an increase in the teaching staff and as will be seen in our advertisement columns applications from qualified medical women are invited. The Government has granted 25,000 rupees for the completion of the hospital and dispensary buildings and the University of Lahore has promised to consider its affiliation as soon as certain requirements are fulfilled, one of which is that there shall be eight fully qualified practitioners (female) on the teaching staff.

ANTITYPHOID inoculation has been introduced into the German Army in view of the favourable results obtained by the application of Dr. A. E. Wright's method. The troops proceeding to South-West Africa in connexion with the military operations which are being conducted there have, we believe, been made the subject of treatment.

THE Revaccination Bill, 1904, has passed its second reading and the committee stage in the House of Lords. Lord Lansdowne, quoting from Dr. Bruce Low's recent report, pointed out that in the last 12 years there had been in Germany only 667 deaths from small-pox in a population of more than 56,000,000.

THE council of the Society of Arts has awarded the silver medal of the society to Dr. Robert Jones for a paper upon Physical and Mental Degeneration which was published in the journal of the society of March 4th.

THE King has been pleased to approve of the appointment of Mr. Otho Galgey, M.R.C.P. Irel. (colonial assistant surgeon), to be an official member of the Legislative Council of the Island of Saint Lucia.

Sir John Wolfe Barry will distribute the certificates and prizes at King's College, London, on Wednesday afternoon, July 6th, at 3 P.M.

H.R.H. the Prince of Wales has consented to become Patron of the Royal Meteorological Society.

THE LAST SCHOOL BOARD REPORT.

(Concluded from p. 1815 of THE LANCET *of June 25th, 1904.)*

WE now come to that portion of the report which treats of the measures adopted under the direction of the School Board for checking the dissemination of diphtheria. This section of the report is written by Dr. C. J. Thomas who has devoted much attention to work of this nature. According to his experience it appears that diphtheria does not tend to spread to any great extent in classes composed of children under the age of four or above the age of seven years. In babies' classes—i.e., amongst children at ages from three to four years—diphtheria has not been found to spread in the London board schools. It is among children between their fourth and seventh birthdays that the greatest danger of school-spread is to be feared. Dr. Thomas suggests the following interesting explanation of this peculiar age incidence. It is well known, he says, that the blood of adults and older children in this country contains an appreciable quantity of antitoxin. It is equally certain that infants have a relative immunity against the disease; children between four and seven years are therefore in the intermediate stage in which, while they have lost the protection acquired at birth from placental circulation, they have not yet acquired immunity by the self-production of antitoxin that is set up by sub-pathogenic doses of diphtheria bacilli.

In the earlier part of last year a laboratory was fitted up and work therein was commenced in June, the experience gained during 1902 and 1903—particularly with regard to the Gordon House Home and Ancona-road outbreaks—having shown that greater facility for bacteriological investigation was essential in order that diphtheria prevalence in schools should be adequately dealt with. The methods adopted at the laboratory are very instructive. They do not, however, readily admit of being summarised and in view of their importance we give the description in Dr. Thomas's own words: "The diphtheria returns from all districts were kept under continuous observation, and as soon as there was any suspicion of school influence, as shown by the attack-rate in any school department or class, a visit was made. The children in the affected classes were examined, and the attendance registers were carefully looked over. All children giving clinical signs of mild diphtheria—e.g., nasal discharge, enlarged cervical glands, undue pallor, ear discharge; children whose attendance record showed a suspicious absence; children whose history was in any way doubtful, e.g., coming from a recently infected house, having returned from hospital, or having recently appeared out of sorts—all such children were examined bacteriologically. This was carried out by transferring a portion of the mucus from the throat or nose by a platinum loop straight on to a sterile serum tube which was afterwards grown at 98° F. for 15 hours. The culture was then examined and any case showing Klebs-Löffler bacilli was immediately excluded from school by telegram, and notified to the local medical officer of health."

As compared with the usual method of "swabbing" with cotton wool the advantages of direct inoculation of serum tubes as now described are: first, that growths are obtained in a larger proportion of cases; secondly, that a more delicate manipulation is secured; thirdly, that the objection to a double transference of material is surmounted;

---

[1] Published by Messrs. Morgan and Scott, 12, Paternoster-buildings, London, E.C.

and lastly, that the expense and trouble of providing sterile swabs are avoided. For purposes of exclusion the tests relied on as conclusive were: (1) the morphological characters (in every case); and (2) the Neisser staining reaction. Other tests, such as (3) acid production; (4) virulence to guinea-pigs; or (5) "unpremeditated virulence experiments" are inadmissible, save *for confirmatory results, owing to the time* necessary for their application. As the children remain at school during the making of the test rapidity of action is obviously a necessity.

As a result of rigorously applying the foregoing method it is satisfactory to find that from August, 1903, to March, 1904, it was not necessary to close any class in a London board school on account of diphtheria and, further, that the spread of diphtheria in the schools of the Board has been arrested. From the fact that out of 758 cases examined only 7·6 per cent. showed diphtheria bacilli it is clear that the experience in London board schools does not confirm the statements sometimes made respecting the prevalence of diphtheria bacilli among the population. In this connexion Dr. Thomas quotes the experiments of Hewlett and Murray who, basing their conclusions on investigations of the throats of children admitted to the Victoria Hospital, argued that 15 per cent., or one in every seven of normal children in the general community, have diphtheria bacilli in their throats.

In London board schools, however, Dr. Thomas has found that only one in 13 children have diphtheria bacilli, even in affected classes where the children must be looked upon as possible "contacts"; amongst "non-contacts" the prevalence must be very much less. And here it is interesting to note the conditions at Gordon House Home. At this residential school a severe outbreak of diphtheria occurred in 1902 which terminated in December of that year. The throats of all the children were systematically swabbed and none of them were allowed to return to the home until they were free from bacilli. In December, 1903, a year after the ending of the outbreak, all the girls' throats were again swabbed with the result that only two were found to be harbouring diphtheria bacilli out of 64 present in the house, the proportion being 3·1 per cent. These bacilli were, moreover, attenuated and non-virulent to guinea-pigs.

A number of bacilli morphologically simulating the organisms of Klebs-Löffler are found in the tonsillar and nasal discharges of a large proportion of London children. These are styled pseudo-diphtheria bacilli and are altogether non-virulent. The biological position of the pseudo-diphtheria bacillus and its relation to diphtheria are not settled. It is regarded as probable that in many of the earlier recorded researches these bacilli were not differentiated and that consequently an exaggerated estimate of the frequency of the diphtheria bacillus has been made. Dr. Thomas tells us that out of 758 examinations the pseudo-diphtheria organism has been identified in 211 cases, or 28 per cent. of the whole. Owing to doubts respecting the relationship of this pseudo-bacillus [illegible] ren was discontinued and it was found that the presence of these organisms might safely be ignored. Nevertheless, we are assured that a certain relationship does exist between the two organisms and—what is of more importance—that where true diphtheria is most prevalent, there are found in greater abundance the pseudo-diphtheria bacilli also. It is probable that the pseudo-organism is totally distinct from the true diphtheria bacillus but that it is a member of the same group, affected by the same conditions and spreading in a similar way from child to child. Its general presence therefore may be useful as indicating the directions in which diphtheria, if introduced, would be likely to spread. It further appears to be probable that the pseudo-bacillus is capable of causing mild sore-throat and in many instances children suffering from sore-throat during a diphtheria outbreak show in bacteriological tonsillar cultures no trace of the Klebs-Löffler bacillus but an almost pure culture of the pseudo-organism. Speaking of the mode in which diphtheria is spread through school attendance Dr. Thomas expresses the opinion that diphtheria is a personal disease and spreads to any serious extent only by personal contact. The common use of slates and of drinking cups may conceivably be a danger but his experience has shown that direct personal transmission is the chief cause and almost the only one to be considered practically. Nevertheless, in order to be on the safe side the use of slates has been discontinued by the London School Board.

Dr. Thomas divides the children who spread diphtheria into two groups: Group A, perfectly healthy children who have not had diphtheria but who have been in contact with [illegible] diphtheria; [illegible] disease, are [illegible] cillus and of transmitting it to others. Such transmitters of the disease are termed "carriers." Group B, children actually suffering from the disease who go to school in an infective condition. This group consists: (1) of children with clinical signs of diphtheria but not ill enough to be kept at home; and (2) of children who have passed through a slight attack of diphtheria and return to school whilst still in an infectious condition. Group A is of the greatest importance, owing to the fact that "carriers" are the most difficult to detect and therefore the most likely to do mischief; they are also the most difficult to deal with after discovery. There is evidently need in London for greater facilities for bacteriological examination than those that at present exist. There can be no prospect of stamping out diphtheria until such facilities are everywhere available. "Contacts" with diphtheria are largely ignored and whilst still infective are permitted to mix with their schoolfellows and with other members of the community. With more frequent use of bacteriological diagnosis in cases presenting slight clinical symptoms and universal employment of the same methods in the case of "contacts" it should be possible in this country to obtain absolute control over diphtheria.

THE METROPOLITAN STREET AMBULANCE ASSOCIATION.

Two influential deputations were received by the police committee of the Corporation of the City of London on June 29th with reference to the ambulance question.

The Metropolitan Street Ambulance Association was represented by Mr. Reginald Harrison, the President, Mr. A. A. Bowlby, surgeon to St. Bartholomew's Hospital, Sir William Church, President of the Royal College of Physicians of London, Sir Dyce Duckworth, physician to St. Bartholomew's Hospital, Mr. Raymond Johnson, surgeon to University College Hospital, Surgeon-General A. H. Keogh, Mr. John Langton, surgeon to St. Bartholomew's Hospital, Sir Stephen Mackenzie, physician to the London Hospital, Mr. Charles Mansell Moullin, surgeon to the London Hospital, Sir E. Cooper Perry, superintendent at Guy's Hospital, Dr. H. D. Rolleston, physician to St. George's Hospital, Mr. Cuthbert S. Wallace, surgeon to St. Thomas's Hospital, Mr. C. H. Golding-Bird, surgeon to Guy's Hospital, Dr. A. W. James, honorary secretary, and the Hon. Dudley Leigh.

The deputation appointed by the central executive committee of the St. John Ambulance Association consisted of the following gentlemen: the Marquess of Breadalbane, Lieutenant-Colonel Sir Richard Temple, Surgeon-General Sir Joseph Fayrer, Surgeon-General Sir W. R. Hooper, Inspector-General B. Ninnis, and Colonel Sir Herbert C. Perrott.

Mr. HARRISON in his opening remarks said:—"We come as a deputation to-day from the Metropolitan Street Ambulance Association (a large body of medical practitioners resident in London) over which I have the honour to preside, to urge upon the Corporation of London the necessity for providing a more efficient ambulance service for the City. In furtherance of this object we have with us representatives from the three hospitals which receive the larger number of accidents occurring within the City of London—viz., St. Bartholomew's, Guy's, and the London Hospital. An independent deputation from the St. John Ambulance Association also accompanies us. In dealing with this object it must be remembered that of the large number of accidents and medical casualties which daily occur in the City many are in connexion with steam and electric machinery. The latter are frequently and increasingly the cause of what can only be described as the most frightful injuries and lacerations that can be conveyed through the streets. Permit me to say that we are specially desirous upon this occasion to urge upon the members of the committee the necessity for providing with as little delay as possible a more rapid and efficient service by the addition of horse ambulances to the existing appliances. By these conveyances not only is prompt and skilled attendance brought to and applied on the spot where the accident occurs but, if necessary, as often happens in cases of serious hæmorrhage and wounds, whilst the patient is in course of transit to the hospital. There would, I anticipate, as in other places where horse ambulances have been used for some years, be no difficulty in efficiently and economically manning them by advanced students connected with the City hospitals which I have mentioned. I will not occupy your time further, but with your permission, Sir, will call upon our secretary, Dr. Arthur James, to make a few remarks or to furnish replies to any questions you may wish to put as supplementary to what I have said."

Dr. JAMES then said: "Medical men who come in contact with cases of accident or sudden illness either as they occur in the streets or as they arrive at hospitals are painfully aware of the fact that under present conditions not only do people die who might be saved but some who would not otherwise die lose their lives entirely through the faulty method of their removal, while many others have their sufferings and their injuries greatly aggravated from the same cause. This condition of things is all the more to be deplored because the remedies are so simple and are so thoroughly proved in every other well-organised city. It is sometimes said that the expense to the community of providing an efficient ambulance service in London would be too great, but it must be apparent that the cost of all this unnecessary loss of life and prolonged disablement and treatment is enormously in excess of what would be required to remedy it. 35 years ago all these points were thoroughly discussed in New York with the practical result that a well-organised horse ambulance was established. The advantages of that service were so obvious that almost every large city in America soon followed that example, and gradually since then most of the best regulated cities of the world have adopted similar methods. It is noteworthy that many of the cities that now have good horse ambulance services at first, from motives of economy, tried to manage with litters but these were soon found to be inadequate and unsatisfactory as is the case in London. The extensive experience of other large cities proves beyond question that for the successful working of an efficient ambulance service the following provisions are essential: 1. That the police should be kept properly trained in first-aid work. 2. That by means of telephones easily reached from the scene of any accident it should be possible to summon an ambulance adequately equipped and in charge of a skilled attendant. 3. That the ambulance should be stationed in a convenient place in touch with the hospitals, ready to start at very short notice and able to reach the scene of the accident accompanied by the attendant within a few minutes. 4. That the vehicle should be so constructed that the attendant can remain close to the patient and able to watch and to administer treatment if necessary during the entire journey to home or hospital."

Sir DYCE DUCKWORTH and Sir JOSEPH FAYRER both laid great stress on the loss of life and unnecessary suffering due to the absence of an efficient ambulance service in London, and said that they were quite ashamed of the chief City of the Empire in this respect.

Sir RICHARD TEMPLE, Inspector-General NINNIS, Sir WILLIAM CHURCH, Mr. BOWLBY, and Mr. GOLDING-BIRD endorsed all that had been said and strongly advocated the establishment of an efficient horse ambulance service.

The deputations were most favourably received and after a very satisfactory interview withdrew.

ASYLUM REPORTS.

Surrey County Asylum, Brookwood (Annual Report for 1903).—The average number of patients resident during the year was 1180, comprising 492 males and 688 females. The admissions during the year amounted to 453—viz., 228 males and 225 females. Of these 296 were first admissions. Mr. J. E. Barton, the medical superintendent, states in his report that the total number of cases admitted "exceeds the admissions in any previous year, with the exception of 1884, since the opening of the asylum. ...... Many possessed insane inheritance or suffered from organic brain disease. Many also were actively suicidal and had made attempts or threats [of suicide] prior to admission and the need of constant supervision and forethought in the treatment of these cases was a source of great anxiety." Two females admitted whilst pregnant were confined during the year, the children being in due course removed by their friends. The difficulty of prompt egress in case of fire from the upper dormitories of the old asylum buildings had long been a source of anxiety. This matter has at last been successfully dealt with. Eight external fire-escape staircases have been fixed, openings have been made where necessary between the dormitories, and internal doors have been made to open both ways and all external doors to open outwards. Other improvements have also been carried out with reference to the water-supply and the heating and warming arrangements of the place. The number of patients discharged as recovered during the year amounted to 95—viz., 46 males and 49 females, or 8 per cent. of the average number resident. The deaths during the year amounted to 111, or 9·4 per cent. as calculated on the same basis. Of the deaths, four were due to renal disease, five each to cardiac disease and epilepsy, six each to cerebral hæmorrhage and pneumonia, 13 each to organic brain disease and senile decay, 16 to pulmonary and other forms of tuberculosis, 21 to general paralysis of the insane, and the rest to other causes. The Commissioners in Lunacy state in their report that the asylum wards were in excellent order, that the condition of the dormitories and bedding was very satisfactory, that the patients were found neatly and suitably clad and in a satisfactory condition as regards personal tidiness, that the dinners served to the patients were good in quality and sufficient in quantity, and that the medical case-books were well and properly kept. The committee of management states in its report that the maintenance rate for patients has been fixed at 12*s.* weekly per head for the whole year, that the extension of the laundry and of the water-supply has been proceeded with, and that the building of an extension to the asylum has just been concluded in a very satisfactory manner, the final adjustment of accounts showing that the work had been executed for £107 12*s.* less than the amounts voted by the Surrey County Council.

Monmouth County Asylum, Abergavenny (Annual Report for 1903).—The average number of patients resident during the year was 950, comprising 485 males and 465 females. The admissions during the year amounted to 220—viz., 118 males and 102 females Of these, 167 were first admissions. Dr. J. Glendinning, the medical superintendent, states in his report that a considerable proportion of the patients admitted were very much debilitated in health and bodily condition and bodily diseases and disorders were given as the cause of the mental disorder in 74 cases. Hereditary predisposition was traced in 43 cases and intemperance in drink in 13 cases. The number of patients discharged as recovered during the year amounted to 86—viz., 41 males and 45 females, or 9 per cent. of the average number resident. The deaths during the year amounted to 95, comprising 44 males and 51 females, or 10 per cent. as calculated on the same basis. Of the deaths three were due to epilepsy, four to pneumonia, five to cerebral hæmorrhage, seven [illegible] insane, 13 each to cerebral softeni[illegible] other forms of tuberculosis, 24 to [illegible] rest to other causes. The deaths [illegible] causes excepting in the case of two male patients; one, a private patient who was allowed out daily on parole, was accidentally killed by being knocked down by an express train while walking over a level crossing on the Great Western Railway, and the other committed suicide by hanging. "The great event of the year was the removal of 228 patients, belonging to the counties of Brecon and Radnor, to their new asylum at Talgarth ...... which was accomplished with but little trouble and without accident." The Commissioners in Lunacy state in their report that the patients appeared to be in good bodily condition and well cared for, that their dress and general appearance were satisfactory, that the dormitories were clean, comfortable, and well ventilated, and that the medical case-books were satisfactorily and well kept. They suggest certain slight improvements to secure a more efficient supply of water in case of fire than the inadequate supply which they witnessed at their visit. The committee of management states in its report that there is now vacant accommodation in the asylum for 76 patients—viz., 26 males and 50 females. Certain parts of the old building have been rebuilt and during the time of the use [illegible] longer period was not san [illegible]

Borough of Leicester Asylum, West Humberstone (Annual Report for 1903).—The average number of patients resident during the [illegible] and 456 females. [illegible] to 241—viz., 75 m [illegible] vere first admissions. Dr. J. E. Montague Finch, the medical superintendent, states in his report that "of the 806 patients remaining in the asylum at the end of the year 29 (13 males and 16 females) were deemed curable." As usual, many of the patients admitted were found to be in an extremely feeble state of bodily health "and the number of those permanently confined in bed continues to increase ...... most of them [being cases of] chronic ill-health and senile decay." Among the chief causes of insanity in the admissions intemperance in drink was ascertained to exist in 21 cases—viz., 18 males and three females, hereditary predisposition existed in 38 cases, and congenital mental defect was present in seven cases." Senile decay was the cause of mental failure in 16 cases. The number of cases discharged as recovered during the year amounted to 65—viz., 33 males and 32 females, or 8·3 per cent. of the average number resident. The deaths during the year amounted to 67—viz., 35 males and 32 females, or 8·5 per cent. as calculated on the same basis. Of the deaths two each were due to epilepsy and renal [illegible] and cancer, six to [illegible] or other forms of [illegible] general paralysis of the insane, and the rest to other causes. The general health of the inmates was good during the year and no inquest was held. Only one serious casualty occurred, that of a feeble epileptic female who broke her leg by falling in a fit. Two new greenhouses have been erected for the purpose of supplying the wards with additional plants and flowers. Steam ironing machinery and other labour-saving appliances have been added to the laundry. A pension scheme for officers and servants of the staff has been adopted. The scale of superannuation after 15 years of service is $\frac{15}{60}$ths of the average amount of salary and emoluments of the officer or servant, with an additional sixtieth for each further year of completed service, the maximum amount not exceeding $\frac{40}{60}$ths. The Commissioners in Lunacy state in their report that the day-rooms and dormitories of the asylum were found to be in excellent condition, that the electric lighting throughout the institution was nearly completed, that the condition of the patients seemed good and that they appeared to be well cared for, and that the medical case-books and registers were carefully and well kept. They recommend that extra exits and increased facilities for escape in case of fire should be provided for the male infirmary dormitory, with the exception of which they regard the existing arrangements as generally very satisfactory. The committee of management states in its report that nearly all the officers and servants of the institution have entered into the necessary agreement for giving effect to the pension scheme, that during the year additional gardens and walks have been laid out for the use of the patients requiring walking exercise, and that the asylum buildings externally and internally are in a satisfactory state of repair.

Royal Asylum of Montrose (Annual Report for 1903).—The average number of patients resident during the year was 677, comprising 313 males and 364 females. The admissions during the year amounted to 145—viz., 58 males and 87 females. Of these, 113 were first admissions. Dr. John G. Havelock, the medical superintendent, states in his report that of the total number resident about 130 were private patients. "The total number of private patients resident at the end of the year shows an increase of ten and the [illegible] patients a decrease of nine." [illegible] as voluntary boarders. Many [illegible] on were found to be in bad bodily health, six had general paralysis of the insane, six others had organic brain disease, seven were affected with pulmonary tuberculosis, nine were in an advanced stage of senile decay, 31 had various affections of the heart and vascular organs, and a few were suicidal, epileptic, or affected with asthma and bronchitis. The number of patients discharged as recovered during the year amounted to 69, or 10·2 per cent. of the average number resident. The deaths [illegible] pulmonary tuberculosis and cerebral hæmorrhage, five to organic cerebral disease (excluding hæmorrhage), nine to general paralysis of the insane, ten to cardio-vascular disease, 11 to senile decay, and the rest to other causes. The only accidents of a serious nature which occurred during the year were a simple fracture of the femur sustained by a fall, and the death of a female patient who had escaped from the buildings at dusk and made her way [illegible] "but," adds Dr. Havelock, "the absence of a complete history of the cases makes it impossible to assign an exact causation. ...... This is specially worthy of mention, as in some of the asylums in Scotland drawing patients from the large towns, excessive drinking has been certified with causing about 50 per cent. of the admissions. ...... The natives of the shires of Forfar and Kincardine are a hard-headed section of the population ...... and many can consume enormous quantities of alcohol over long periods of years without showing .. actual insanity." The Commissioners in Lunacy state in their report that the wards in the main building, the hospital block, and the male villa were maintained in excellent order, that the day-rooms and dormitories were bright and cheerful, that the former were well supplied with books, plants, and objects of interest, that the bedding was [illegible] condition, that the lavato[illegible] ere of the newest and best [illegible] of the patients was highly satisfactory and indicative of capable and conscientious care, and that the medical records and case-books were well and intelligently kept. The private patients in Carnegie House were "surrounded with every comfort, its accommodation being throughout of exceptional excellence."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8509 births and 3867 deaths were registered during the week ending June 25th. The annual rate of mortality in these towns, which had been 14·6, 14·2, and 13·8 per 1000 in the three preceding weeks, further fell last week to 13·2 per 1000. In London the death-rate was 12·8 per 1000, while it averaged 13·4 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 4·7 in Willesden, 7·0 in King's Norton, 7·1 in Aston Manor, 7·4 in Wolverhampton, 7·8 in Wallasey, 8·0 in East Ham and in Stockton-on-Tees, 8·3 in Hornsey, and 8·6 in Walsall and in Smethwick; while the highest rates were 17·8 in Liverpool and in Warrington, 18·3 in Stockport and in Oldham, 18·6 in West Bromwich, 18·9 in Middlesbrough, 20·0 in Sunderland, 22·0 in Bootle, and 22 3 in Birkenhead. The 3867 deaths in these towns last week included 444 which were referred to the principal infectious diseases, against 495, 492, and 487 in the three preceding weeks; of these 444 deaths, 180 resulted from measles, 84 from whooping-cough, 75 from diarrhœa, 48 from diphtheria, 27 from scarlet fever, 26 from "fever" (principally enteric), and four from small-pox. In Willesden, Norwich, Devonport, Wolverhampton, Aston Manor, York, Swansea, and in nine other smaller towns no death from any of the principal infectious diseases was registered last week, whilst the highest death-rates from these diseases were recorded in Brighton, Birkenhead, Liverpool, St. Helens, Warrington, Oldham, Burnley, and Hull. The greatest proportional mortality from measles occurred in Brighton, Birkenhead, Wallasey, Liverpool, Bootle, St. Helens, Manchester, Oldham, Burnley, Halifax, and Hull; from scarlet [illegible] Warrington, [illegible] teshead. The [illegible] om diarrhœa [illegible] large towns. Of the four [illegible] these towns last week [illegible] thamstow, one to Stock- [illegible] The number of small-pox patients under treatment in the Metropolitan Asylums Hospitals, which had been 96, 95, and 80 at the end of the three preceding weeks, had risen again to 83 at the end of last week; 16 new cases were admitted during the week, against ten, 21, and seven in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, June 25th, was 1629, against 1673, 1647, and 1630 on the three preceding Saturdays; 199 new cases were admitted during last week, against 207, 193, and 206 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 181, 157, and 142 in the three preceding weeks, declined last week to 141, and were nine below the number in the corresponding period of last year. The causes of 29, or 0·8 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Leicester, Salford, Bradford, Leeds, Newcastle-on-Tyne, and in 51 other smaller towns; the largest proportions of uncertified deaths were registered in Reading, Liverpool, Huddersfield, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·1, 16·2, and 17·0 per 1000 in the three preceding weeks, declined again to 15·9 per 1000 during the week ending June 25th, but was 2·7 per 1000 in excess of the mean-rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·3 in Leith and 14·6 in Aberdeen, to 18·0 in Paisley and in Greenock and 21·1 in Dundee. The 526 deaths in these towns included 27 which were referred to whooping-cough, 22 to diarrhœa, 12 to measles, six to diphtheria, four to "fever," two to scarlet fever, and one to small-pox. In all, 74 deaths resulted from these principal infectious diseases last week, against 64, 73, and 66 in the three preceding weeks. These 74 deaths were equal to an annual rate of 2·2 per 1000, which was 0·7 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 21 in each of the two preceding weeks, increased last week to 27, of which 13 occurred in Glasgow, five in Edinburgh, three in Dundee, two in Aberdeen, and two in Paisley. The deaths from diarrhœa, which had been 14, 24, and 20 in the three preceding weeks, rose again to 22 last week, and included nine in Glasgow, seven in Dundee, two in Aberdeen, and two in Greenock. The fatal cases of measles, which had been 16 and 14 in the two preceding weeks, further declined last week to 12, of which five were registered in Glasgow and four in Edinburgh. The deaths from diphtheria, which had been four in each of the two preceding weeks, increased to six last week, and included two in Glasgow and two in Edinburgh. The fatal cases of "fever," which had been two in each of the two preceding weeks, rose last week to four, of which two occurred in Dundee. The death from small-pox belonged to Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 87, 68, and 93 in the three preceding weeks, declined again last week to 64 and were 28 below the number in the corresponding period of last year. The causes of 14, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·7, 18·3, and 21·7 per 1000 in the three preceding weeks, declined again to 19·5 per 1000 during the week ending June 25th. During the past four weeks the death-rate has averaged 19·8 per 1000, the rates during the same period being 13·0 in London and 15·6 in Edinburgh. The 142 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 16 from the number in the preceding week and included three which were referred to the principal infectious diseases, against 16, four, and six in the three preceding weeks; of these, two resulted from diphtheria and one from measles, but not any from small-pox, scarlet fever, whooping-cough, "fever," or diarrhœa. These three deaths were equal to an annual rate of 0·4 per 1000, the death-rates last week from the principal infectious diseases being 1·4 in London and 1·9 in Edinburgh. The 142 deaths in Dublin last week included 18 among children under one year of age and 38 among persons aged 60 years and upwards; the deaths of infants showed a considerable decline, while those of elderly persons were slightly in excess of the number in the preceding week. Five inquest cases and three deaths from violence were registered; and 50, or more than a third, of the deaths occurred in institutions. The causes of three, or more than 2 per cent., of the deaths registered in Dublin last week were not certified.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are some additional principal amounts received at the Mansion House on behalf of the Hospital Sunday Fund. The total of the sums paid in up to Wednesday evening amounted to £38,000, to which, of course, will be added Mr. Herring's generous contribution of 5*s*. in the £.

Argyll and Sutherland Bearer Company: William Cochrane Murray, to be Lieutenant (dated June 25th, 1904).

THE HOUSES OF PARLIAMENT AND WAR OFFICE RECONSTRUCTION.

The recent debate in the House of Lords on War Office Reconstruction led to some important statements on the part of Lord Lansdowne and Lord Donoughmore which will serve to indicate in a general way the view entertained by the Government in respect to the report of Lord Esher's Committee on that subject. Whilst agreeing in many ways with its aim and general principles it is clear from what their lordships said on behalf of the Government that Ministers do not by any means hold themselves bound by everything that appears in that report and on some points even emphatically dissent from it. But the discussion in the House of Peers, however interesting in itself, does not touch the scheme of army reform which has still to be drafted and laid before Parliament. There was a lively debate on Army Reform in the House of Commons on Tuesday last, started by Mr. Beckett. Some important and instructive information was elicited from Mr. Arnold-Forster and from the Prime Minister. The country, no doubt, is keenly interested in the production of the long-expected scheme of army reform, but it cannot be denied that the problem to be solved is difficult and complex and so long as it is honestly tackled the nation will not grudge any reasonable delay in making public the scheme. Mr. Arnold-Forster does not despair of putting a scheme before the country in a fairly complete form or of getting an army suited to the requirements of the Empire at a reduced rate of army expenditure.

THE BIRTHDAY HONOURS.

The names of members of the medical profession who are included in the list of birthday honours will be found in another part of the present issue of THE LANCET. The list includes the following officers connected with the services: Deputy Surgeon-General J. H. Thornton, C.B., I.M.S. (retired), and Surgeon-General E. Townsend, C.B., C.M.G., A.M.S., who have been promoted to Knight Commanderships of the Bath, and Surgeon T. Ligertwood (retired pay), late physician and surgeon to the Royal Hospital, Chelsea, Surgeon-General W. J. Fawcett, A.M.S., and Hon. Colonel J. E. Squire, R.A.M.C. (Volunteers), London Companies, who receive Companionships of the same Order.

THE WAR IN THE FAR EAST.

Since the fiercely fought battle of Telissu with such disastrous results to the Russian forces Admiral Togo's naval victory at Port Arthur has to be recorded. Without entering into the details connected with the attempt of the Russian fleet to escape it may be said that the attempt failed. The circumstances were very similar to those which took place in February last. The Japanese torpedo flotilla was launched at night against the Russian fleet, the Japanese *battle-ships keeping outside* the mine area. The dire results as regards the Russian fleet are well known. The attempted sortie from Port Arthur ended in disaster and Admiral Togo's fleet purchased a victory at a relatively insignificant cost. Nor can it be said that the progress of the events on the land side has been more favourable to the Russians. The strategical outlook from a Russian standpoint is not a promising one and it is not surprising to learn that fears are entertained in Russia that General Kuropatkin is not ready at the present time to cope with the advancing enemy. Whether he will seek by a rapid northward march to escape from the Japanese fast closing in upon him or will concentrate his forces and make a big fight of it somewhere about Tashichao now remains to be seen. If the Japanese have captured three passes General Kuropatkin, unable to retreat northward, may be compelled to fight or to surrender. Be all this as it may, there must soon come an end to speculation for the season is fast approaching when there must be a *temporary suspension* of all active hostilities. This fact must be well known to the Japanese and we may consequently be sure that they are now only waiting until the disposition of their forces *is such as* to enable them to strike with what they consider likely to be to the best advantage to themselves. We learn but little of the medical history of the campaign and what we do is rather conflicting. We shall probably know next to nothing of a trustworthy kind on this head until the war is over. The troops of the first Japanese army are reported to be in good health and spirits. Native reports from Niu-chwang state that the Russians are losing many horses from glanders. On June 24th there were 800 wounded at the Russian camp *three miles east of Niu-chwang. A few surgeons of the Red* Cross Society had arrived there but many more are needed. Local medical men are offering their assistance which the Russians decline. At the battle of Telissu the behaviour of the medical men and ambulance attendants who remained the whole time under fire with the Russian troops is described as having been admirable. The losses on the part of the Russians on that occasion were very large and turn out to have been much in excess of what was originally reported. General Oku reports: "Russian corpses buried by us near Telissu up to evening, June 17th, amounted to 1516. Russian corpses still forthcoming and believed to increase considerably. Natives say Russians during engagement carried back their killed and wounded by railway, while later, when about taking flight, they buried or cremated corpses near Huasungkou." The hardships of the retreat of the unhappy Russian soldiers following the battle of Telissu were terrible owing to the fatigue, want of food, exposure, and heavy rains after their two days of hard fighting. It is a notable feature of this war that the loss of Russian officers under fire has, as compared with men, been so disproportionately large.

The *Kharbin Viestnik* observes that near Tchita on the river Peschanoı the building of a large hospital to accommodate 5000 patients has been begun. It will consist of 25 buildings each to take in 200 beds exclusive of other buildings for the staff and stores.

The *Sviet* gives the following as the financial state of the Russian Red Cross Society on June 1st. The total in hand was £737,087. For special account of the Russo-Japanese war it had received £356,222 and paid out £298,925, balance £57,296 less a fraction. Besides this there is a reserve capital for the pressure of war time of £227,951. The May receipts were £117,341 and the payments were £82,756.

Correspondence.

"Audi alteram partem."

THE INFLUENCE OF THE UNRECOGNISED CASE IN THE SPREAD OF COMMUNICABLE DISEASE.

To the Editors of THE LANCET.

SIRS,—There is a statement and there is a deduction in your otherwise admirable leading article under the above heading in THE LANCET of June 11th, p. 1666, to which exception will be taken by those who have given special attention to the "isolation" question. As to the first it will be felt that the comparison of such with ignorant and unreasoning antivaccinationists can hardly hold in view of the fact that all the objections to the aggregation system have been raised on purely scientific grounds—unless, indeed, the word "science" has been modernised out of its etymological signification. Usefulness is a tangible thing and if "these useful institutions" are rendering any service to the community how is it that no data are forthcoming in support of such a claim? Not only has no man ever yet attempted to justify the existence of the isolation hospital on scientific lines but nobody has dared to excuse it. And good reason why; for, on the one hand, we have the inexorable facts of secondary infection, post-scarlatinal diphtheria, return cases, and endemic scarlet fever, with numerous formidable aggregation et ceteras; on the other—what? a guess, a surmise—a guess with a memory so short that it forgot the teachings of experience, from the old Edinburgh fever house downwards—a surmise so crude that it was able to ignore the findings of bacteriology. So the spectacle presented to the world is that of the defeat of the objects and aims of sanitary betterment by a system designed as a preventive measure.

Turning to the part played in the spread of disease by the unrecognised case I submit, Sirs, with deep respect, that a very different lesson may be read into your article from the one you seek to inculcate. Were the world not already weary of registrations, notifications, "isolations," State regulation, and compulsion, would the harassing and costly espionage suggested in your article minimise the evil? I aver that it would not. Diphtheritic bacilli flourish in the throats of healthy people. Numbers of cases of scarlet fever remain unrecognised until the peeling stage and after, and my experience as public vaccinator has shown me that small-pox may run its course without rash and without any marked malaise. And where would the bacteriologist come in in any of the three diseases? In diphtheria where the presence of the organism does not necessarily predicate the existence of the disease nor its absence negative it? Scarlet fever and small-pox? in one of which the *materies morbi* is undiscovered and in the other only guessed at. We claim, Sirs, that the unrecognised case is but one of the many rifts in the lute which there is no mending. More frightening would mean more concealment and notwithstanding the tact and gentleness with which the sanitary officials have discharged their onerous duties it is concealment that has kept the epidemic of small-pox going in this city since January last. The present somewhat alarming recrudescence is entirely due to a concealed case.

The concluding paragraph of your leading article makes one wonder why much of the rest was written. "A careful study of the conditions which have led almost to the extinction of typhus fever and to the decline of tuberculosis in this country may perhaps help us to make greater resistance to other infectious diseases." They are wise words and I commend them to the consideration of those public health enthusiasts who see no brighter and better fate in store for their fellows than incarceration in a limbo which would make life not worth living. For these great happenings we are in debt neither to spying, collective "isolation," nor restrictive laws, but to works of sanitation and general sanitary betterment which left law-abiding individuals free from State interference and worrying espionage.

I am, Sirs, yours faithfully,
Nottingham, June 24th, 1904. EDWARD DEAN MARRIOTT.

APPLIANCES FOR PREVENTION OF MINERS' PHTHISIS.

To the Editors of THE LANCET.

SIRS,—With reference to annotations in THE LANCET *re* prevention of miners' phthisis I should like to call your attention to the following facts. Any remedy proposed must not interfere with the efficiency of the boring machine; there must be no substituting of an inferior machine for a better one. Now the water drill is much inferior to the air drill in efficiency and it is not reasonable to expect the managers of mines or even the miners on contract work to use a drill which will give them less returns of ore and consequently less pay. Through the courtesy of the Climax rock drill manufacturers I have had the opportunity of seeing Britten's appliance and also the Climax atomiser and will describe the superiority of the latter. From my observations when seeing Britten's device at work during the drilling of a dry hole I came to the conclusion that although the dust arising therefrom was partially wetted it was not wholly so, with the consequence that the partially wetted dust appeared to be blown about in the immediate neighbourhood of the hole to such an extent that the partly damped particles settled very readily on surrounding objects, including, of course, the men themselves.

It seems to me that an apparatus of this sort employs too much compressed air and not sufficient water, with the result that the water used does not sufficiently damp the dust to drop it in the form of mud or sludge and that the apparatus employing, as before stated, a rather large quantity of air is inclined to blow the partly wetted particles of dust all over the immediate vicinity of the rock drill, and as it does not drop immediately to the ground will be liable to be inhaled by the men employed on the rock-drilling machines.

Now, the device of the Climax rock drill (admitted by the Royal Commission of inquiry as to trade in South Africa to be the only serious English competitor) has many advantages over Britten's. The volume of air used is much smaller, the quantity of water sprayed against the orifice of the dry hole is much larger, so that the particles of [illegible] wetted and drop in practically a vertical [illegible] of the hole being drilled. This appara[illegible] Rock Drill Co. of Carn Brea can be regulated to employ water in variable quantities. It can spray water at the rate of one gallon in five minutes or one gallon in 80 minutes. It also has the unique advantage of being able to employ the same water many times over and is entirely controlled by the air tap of the rock drill, so that both the rock drill and the spray are operated by the one rock drill man, obviating the employment of a second man to hold the water jet, as in the old methods. The machine itself cannot be operated without the spray being also operated, as it is attached to the air tap of the drill and the miner cannot possibly work one without the other.—I am, Sirs, yours faithfully,

JOHN HERBERT TONKING,
Surgeon, Miners' Hospital.
Camborne, Cornwall, June 25th, 1904.

HYDROGEN PEROXIDE AS A GERMICIDE IN TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—In making a number of experiments lately on the influence of antiseptics on digestants and infective microbes in conjunction with Dr. J. L. Dimond, pathologist to the Liverpool Royal Southern Hospital, we were particularly struck with the effect of hydrogen peroxide solution. In comparatively small quantities—20 minims in one ounce of water—this caused complete sterility of the bacillus typhosus. Many years ago Brieger demonstrated the small degree of virulence of the toxin of this bacillus when cultivated on pure peptones and ever since reading his results I have supported my hospital patients—I think with great advantage—on these nutrients. If we possess in hydrogen peroxide, as I am persuaded we do, a harmless but efficacious germicide in typhoid fever we can attack the *causa morbi* in a double direction. As I do not remember to have seen in the general advocacy made by the late Sir B. W. Richardson and others of the germicidal effects of the drug a notice of its influence on the particular bacillus in question I venture to commend its trial to medical [illegible]

Liverpool, June 22nd, 1904. [illegible] ARTER.

A CHRONIC NEUROSIS CHARACTERISED BY FREQUENT PAROXYSMS OF PAIN, SWELLING, AND HÆMORRHAGE IN VARIOUS PARTS OF THE BODY.

To the Editors of THE LANCET.

SIRS,—An original article by Dr. T. K. Monro and Dr. A. N. McGregor dealing with this subject appeared in THE LANCET of April 16th, p. 1039, just to hand. A condition similar in many respects and which at the time was a cause for much speculation occurred in a patient, a single man, aged 26 years. He was under my treatment for pulmonary tuberculosis, both apices showing evidence of disease. A week after he was first seen swelling and severe pain occurred in the left knee. The pain was very intense down the front of the leg to the foot. Four distinct swellings appeared, reddish blue in colour, non-pitting and elastic on pressure, but extremely painful, two on the outer side of the leg, one over the tibia, and one on the calf. On the thigh of the same side two larger swellings approaching the size of an orange appeared a day later. These were not so painful. The knee was red and warm and fluid was present in the joint. Fomentations were applied and the limb was elevated on a splint and the swellings subsided in a week, leaving a brownish staining which entirely disappeared in three or four weeks, though pain still was present on movement. The knee also became reduced in size though some fluid was still present.

In three months he had another attack with rise of temperature to 101° F., accelerated pulse, and vomiting. On this occasion both legs and arms were affected, the left knee being more swollen than the right. Swellings were noted at irregular intervals. They were at first white in colour like the surrounding parts but quickly became dark red. Pain was severe and only slightly relieved by fomentations and sedative applications. One swelling, which was fluctuant, situated on the tibia below the knee on the inner side of the leg, I incised and found a quantity of gelatinous matter of a reddish white tinge. There was little bleeding and the wound healed perfectly after one dressing. Under the microscope only leucocytes and fibrin could be seen with a few red blood corpuscles. No subsequent swelling occurred in that region. At the end of a week the temperature fell to normal and the swellings subsided and the patient's condition improved though he had considerable difficulty in flexing the knees and ankles. He was sent into the country for six months and on his return to Melbourne he again came under notice, having spat up some dark blood on the previous night. An examination of the lungs showed much improvement. He had gained weight and felt well with the exception of severe pain in the region of the left sciatic nerve. The right knee on this occasion was swollen and contained fluid but was not painful. He was sent to the sanatorium but after two months was sent to town for operation on the right knee. There were redness and swelling with fluctuation two and a half inches below the joint and severe pain down the leg. This disappeared after a few days, so operation was considered unnecessary. He was then able to resume his ordinary occupation but had to use sticks to enable him to move about, both limbs being stiff and painful.

Three months later he was a spectator on a stand and missing his footing he fell down steps a distance of 12 or 13 feet. Beyond a slight shock he experienced no inconvenience and next day was in some remarkable, almost incredible, way able to walk and to move as well as ever he could. He has improved in condition and is now engaged in his business, the lung disease having apparently become quiescent.

At the time of these attacks I was inclined to the belief that they were due to angio-neurotic œdema or purpura rheumatica. There was no hæmophilia nor evidence of purpura hæmorrhagica, and urticaria could not be considered as there were no wheals or itching. Although there was no hæmorrhage from the bowel or hæmoglobinuria as described by Wende the symptoms seemed to point more to œdema angio-neuroticum than purpura rheumatica as there was no constitutional disturbance or petechial painful crops as generally found in the latter disease. The condition and its termination (it is 12 months since the accident) are very interesting.

I am, Sirs, yours faithfully,
Melbourne, Australia, May 24th, 1904. ROBT. H. STRONG.

SHOULD MEDICAL MEN BE ALLOWED TO DISPENSE THEIR PRESCRIPTIONS OR NOT?

To the Editors of THE LANCET.

SIRS,—THE LANCET of June 18th contains a letter inquiring whether medical men should be allowed to dispense their prescriptions. Your correspondent is evidently of opinion that apart from the question of prohibition, which has for the time ceased to be a question, it is preferable that medical men should dispense. He quotes two instances which he takes to prove the inefficiency of certain druggists in this part of their business. Once he sent for nitrite of amyl (in capsules). The druggist had none. We are not informed whether he was without the nitrite itself. He had "something that would do as well." There are, of course, other drugs which are used for the same purpose, such as trinitrin. Perhaps it is not unworthy of note that your correspondent himself appears for the moment to have exhausted his own supply. On another occasion he prescribed nepenthe but with a like result. Many druggists keep this preparation; others, as well as probably the majority of practitioners, do not, for nepenthe is not to be found in any British Pharmacopœia. It is simply a proprietary article, one of a thousand stock medicines by means of which, aided not a little by the dispensing system in medical practice, manufacturers of drugs are gradually capturing both the practitioner and the retail druggist. I do not consider, Sirs, that your correspondent's cases are sufficient to justify his sweeping condemnation of the latter. At the same time I admit that many drug-shops are not so fully stocked with all the requisites of treatment as they should be. The reason is clear: so long as medical men continue to dispense demands upon the druggist will be comparatively few. Let them cease dispensing and they will allow an expansion of trade which will insure that the druggist maintains a supply adequate to the needs of his customers. The prices quoted by your correspondent must be extreme in any place. In this part of London *1s.* is about the usual charge for dispensing a prescription. I think there can be very little doubt that the educated druggist of to-day is as a rule what he certainly ought to be—the fittest person to carry out that work of dispensing for which he has been carefully and expressly instructed.

I am, Sirs, yours faithfully,
Highbury, London, N., June 27th, 1904. B. G. MORISON.

THE INSURANCE OF MEDICAL MEN AGAINST THE DANGERS OF THEIR PROFESSION.

To the Editors of THE LANCET.

SIRS,—Dr. J. Eyre's unfortunate experience as described in THE LANCET of June 25th, p. 1811, entirely bears out my own experience as regards the accident policies issued by Scottish companies. On four occasions, and only four, I have had to certify for accidents incurred by holders of Scottish policies and each time the claim has been disputed, and if allowed at all only paid after a good deal of difficulty. One case in particular I remember when a Scottish office absolutely refused to allow a "total disablement" claim which was paid without demur by an English company. Nothing would induce me to take out a Scottish accident policy for myself and I always advise anyone whom I know to hold one to drop it and take a policy in a well-known English company instead. I do not remember that I have ever had a claim disallowed in an English office.

I am, Sirs, yours faithfully,
Plymouth, June 25th, 1904. C. E. RUSSEL RENDLE.

THE NOMENCLATURE OF THE SIGMOID FLEXURE.

To the Editors of THE LANCET.

SIRS,—I notice that in the last edition of Sir Frederick Treves's "Manual of Operative Surgery," vol. ii., p. 291, the author and his colleague, Mr. Jonathan Hutchinson, jun., have perpetuated an error into which Sir Frederick Treves fell when writing his "Anatomy of the Intestinal Canal and Peritoneum." On p. 61 of that work Sir Frederick Treves suggested that the form of the sigmoid flexure was rather that of the Greek capital letter Omega with which we are all familiar, and that the name of this coil of bowel might with advantage be correspondingly altered.

Permit me to point out that the sigmoid flexure takes its name from a form of the Greek letter Sigma which resembles the capital Omega laid on its side, or our modern capital letter O with a little hook added below. This form of Sigma will be found in all the old Greek books in which contractions are used in the type and it has disappeared from modern ones; whence Sir Frederick Treves's error. The editors of the various editions of Quain's Anatomy take care to give the [illegible] index to that work (for example, ni[illegible] The sigmoid notch of the lowe[illegible]vities of the ulna and lower end of the radius are consequently correctly named.

With regard to the sigmoid flexure this matter is far from having a merely academic interest and that is my reason for this communication. Sir Frederick Treves is quite right in pointing out what is the actual shape of this bend of the bowel because arguments for and against the use of O'Beirne's tube which I have read in medical literature have evidently been affected by the conception formed in the mind of the arguer of the exact form of this part. In his work on "Intestinal Obstruction" Sir Frederick Treves shows himself quite sufficiently alive to the dangers of what he terms "the long tube" as a means of diagnosis (second edition, p. 319). He rightly describes the part as a *loop* provided with an extensive mesocolon, in some examples amounting to from 18 to 20 inches in length and capable of touching the gall-bladder, the cæcum, or the umbilicus. The importance in everyday practice of keeping in the mind a correct conception of this part of the intestine is obvious and I think the practitioner will be greatly aided if he remembers the sigmoid cavities of the radius and ulna and why they are so called.

I am, Sirs, yours faithfully,
J. B. NIAS, M.D. Oxon.

Rosary-gardens, S.W., June 22nd, 1904.

THE ROYAL ORTHOPÆDIC HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I am instructed by the committee of the Royal Orthopædic Hospital to inform you, with reference to the circular issued by the secretary of the City Orthopædic Hospital dated Jan. 14th, 1904, that the statement contained in that circular to the effect that the Royal Orthopædic Hospital *has ceased to exist is entirely untrue. As you have* been informed, the Royal Orthopædic Hospital is amalgamated with the National Orthopædic Hospital under the sanction and with the strong approval of King Edward's Hospital Fund for London.

Arrangements have been made for the erection of a new building in which the work of the combined institution will be carried on under one management. In the meantime the work of the Royal Orthopædic Hospital is being carried on in temporary premises at 55, Bolsover-street, W., where both in-patients and out-patients continue to be received. So far as my committee can learn, not one patient of the Royal Orthopædic Hospital has gone to the City Orthopædic Hospital and the suggestion that the amalgamation has in any way increased the work of the City Orthopædic Hospital is without foundation.—I am, Sirs, yours faithfully,

TATE S. MANSFORD, Secretary.

Royal Orthopædic Hospital, 55, Bolsover-street, W., June 27th, 1904.

THE GOVERNMENT OF INDIA AND THE ROYAL ARMY MEDICAL CORPS.

To the Editors of THE LANCET.

SIRS,—Paragraph 429 of the Regulations for the Allowances of the Army, 1903, reads as follows:—"Married officers when necessarily employed on duty with troops on board ship will be entitled to free accommodation for their wives and children, if permitted to accompany them." With regard to India, to which place a very large percentage of the officers of the Royal Army Medical Corps go, this regulation is got over in the following manner. About last January a letter was received by the Director-General of the Army Medical Service from the War Office directing that in future only bachelor officers were to be detailed for duty with troops for India. This must have been done at the instance of the Indian Government. A married officer of the Royal Army Medical Corps with three children thus loses at least £150 over each voyage to or from India, as shown by the following table:—

	Per P. and O. steamboat. £	Per hired transport.		£	s.	d.
Self	52	... ...			*nil.*	
Wife	52	... ... 20 days' messing at	5s. 6d.	5	10	0
Child 8 years old	26	... ... ,, ,,	4s. 0d.	4	0	0
,, 5 ,,	26	... ... ,, ,,	2s. 6d.	2	10	0
,, 4 ,,	26	... ... ,, ,,	2s. 6d.	2	10	0
Nurse (2nd class)	32	... ... ,, ,,	2s. 6d.	2	10	0
Total ...	£214	Total ...		£17	0	0

Deducting from the £214 the £17 for messing on board the transport and the £47 10s. received from the Government the above-mentioned officer loses quite £150, taking into account the lesser cost of extras on board the transport. As a medical officer will in ordinary course perform three journeys to and from India in seven years he would lose at least £450 in this short period. Moreover, when he reaches India he probably has at least one expensive move in front of him in his new command.

Veterinary officers, in accordance with paragraph 426 (*b*) of the Allowance Regulations are always entitled to free passage for their wives and families whether travelling with or without troops. As may be seen, this invidious distinction is a cruel hardship on the medical officer. Regimental officers, as a rule, travel with troops and accordingly are allowed free passages for their families.

The Government of India has recently (May 7th, 1904) ruled that an officer of the Royal Army Medical Corps transferred to a station carrying a higher rate of charge allowance must be viewed as transferred to a more lucrative appointment for the purpose of paragraph 103 (2) of the Army Regulations of India, vol. x. According to this ruling a medical officer landing at Bombay and ordered to Quetta as a specialist at Rs. 50 a month may be put to the expense of Rs. 1000 over the journey of his family and very likely would regret the day he became a specialist. The same thing happens in the case of an officer transferred, say, to an appointment with an increase of charge pay of Rs. 60 a month, the expense of the journey possibly amounting to much more than the total sum received over the larger rate of charge pay. If, say, an officer moves from Darjeeling to Dinapore to assume charge of a station hospital with an extra Rs. 60 per month charge pay he is never likely to be able to recoup himself for the great expense of the journey of his family. If these moves occurred at the officer's own wish one might possibly be able to understand it. In fact, the senior or specialist officer will often prefer to remain in the lower-paid appointment, but unfortunately will not always be allowed to.

The Government of India recently raised the pay of certain of the ranks of the Royal Army Medical Corps after great pressure but by the above new rules it will more than recoup itself for its great generosity.

I am, Sirs, yours faithfully,
QUATUOR MARIA.

THE ROYAL HOSPITAL FOR INCURABLES AND THE DISPUTED LEGACY.

To the Editors of THE LANCET.

SIRS,—Your issue of Dec. 5th, 1903, p. 1611, contains a paragraph headed "Inaccurately Worded Legacies." In this paragraph particulars are given of a then recent decision by a judge of first instance in the Chancery Division to the effect that the British Home and Hospital for Incurables at Streatham was entitled to receive a legacy expressed by a testatrix to be given to "The Royal Home for Incurables, Streatham," and which had then already been paid to the Royal Hospital for Incurables at Putney by the testatrix's executors.

The board of the Royal Hospital for Incurables desire us to acquaint your readers with the following facts. First, that the decision in question was in the month of March reversed by an unanimous decision of the Court of Appeal, and the institution which they represent was held to be entitled to the legacy; and, secondly, that besides the evidence of the donor's intention, legally admissible, there existed in the executors' control additional evidence, not legally admissible, but leaving no moral doubt as to the institution which it was the testatrix's intention to benefit. It has recently come to the knowledge of the board of the Royal Hospital for Incurables that the paragraph from your paper has been reprinted and circulated. As this states the facts only up to a certain point the board think it desirable that the additional facts above detailed should be before your readers and hence we would ask you to permit the insertion of this letter in your next issue.

We are, Sirs, yours faithfully,
FARRER AND CO.

Lincoln's Inn-fields, London, W.C., June 27th, 1904.

FIFTY YEARS OF PAROCHIAL MEDICAL SERVICE.—Mr. Robert Girvan, L.R.C.S. Edin., who was appointed to his present position as medical officer to the Parish council of Maybole, N.B., on June 7th, 1854, has been congratulated by the chairman on behalf of the council on the occasion of his jubilee, the chairman also expressing the appreciation of the council of the thorough and conscientious manner in which he had always performed his duties. Mr. Girvan served for 35 years in the 2nd Volunteer Battalion Royal Scots Fusiliers and retired with the rank of Surgeon-Lieutenant-Colonel, being awarded the volunteer decoration. It is entirely owing to Mr. Girvan's retiring disposition that no public ceremony has taken place to mark his 50 years of parochial service.

THE FOLKESTONE PUBLIC HEALTH CONGRESS AND THE SANDGATE SCANDAL.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Concluded from p 1754 of THE LANCET *of June 18th, 1904.)*

SANATORIUMS IN SWITZERLAND, DENMARK, AND HOLLAND.—RESTRICTIVE LEGISLATION IN NORWAY.—THE CAUSES OF THE PROGRESS IN ENGLAND AND GERMANY.

CONSIDERING the world-wide renown acquired by such places as Davos, Switzerland may be placed in the forefront when dealing with the question of sanatoriums for the treatment of pulmonary tuberculosis It does not seem, however, as if any very remarkable improvement had been effected. The statistics are given in averages for five years and according to these figures the deaths from tuberculosis of the lungs and of the larynx amounted annually to 22·15 per 10,000 inhabitants from 1878-82, to 22·77 during the next five years, and to 22·23 and 22·28 during the following two groups of five years. It may therefore be said that from 1878 to 1897 the fluctuations showed no definite sign of improvement. It is only during the four years from 1898 to 1901 that there is a distinct change for the better, as the annual average for these four years is 19 42 per 10,000 inhabitants. It is, however, very difficult to connect this slight improvement with the sanatoriums as there were many other influential causes at work. The figures also are very scattered and there does not seem to be any comprehensive summary in existence. This is but natural when it is remembered that the Swiss Confederation is subdivided into 22 different constitutions, and further, that nearly all the work has been done by private enterprise. Dr. F. Schmid, Director of the Federal Sanitary Bureau at Berne, does, however, give a list of the popular sanatoriums existing at the beginning of 1903 and their cost. At Heiligenschwendi, 1140 metres above the sea, there has been since 1895 a sanatorium of 108 beds which cost £201 per bed, and a pavilion holding 40 beds has since been added. At Davos the "in der Stille" sanatorium, founded in 1896 by the Basle Society of Public Utility, is 1660 metres above the sea, has 86 beds, and cost £263 per bed In the canton of Zürich the Wald sanatorium is 907 metres above the sea and since 1898 has 90 beds which cost £243 each. At Braunwald, canton Glarus, 1180 metres above the sea, there is a sanatorium of 30 beds which was opened in 1897 and cost £255 per bed. The only instance where the cost was less than £200 is that of a small sanatorium of 22 beds at Malvilliers, in the canton of Neuchâtel, 860 metres above the sea, and in this exceptional case the cost per bed is set down at £181. There are 100 beds in the sanatorium of Leysin and 65 at Clairmont-sur-Sierre. The cantons of Lucerne, Zug, Fribourg, Soleure, [illegible] St. Gall, Aargau, an[illegible] but some £40,000 ha[illegible] toriums [illegible] they [illegible] with [illegible] retain, some beds for their own patients.

By the side of the provision thus made for the Swiss who suffer from tuberculosis there are a large number of popular sanatoriums founded, peopled, and supported by foreign nations. Thus, there are at Davos a Dutch sanatorium with 50 beds, a German sanatorium with 80 beds, and the English invalids' home with 14 beds. There are also a large number of private sanatoriums for the wealthy of all countries at Davos, Arosa, Leysin, and Montana which contain altogether about 1500 beds. Dr. Schmid pointed out in his report on this subject that all the popular sanatoriums of Switzerland have been created by private initiative. The Society of Public Utility has done most in this direction. The communes, the trade corporations, and charitable persons have subscribed funds or guaranteed annual [illegible] loans or given grant[illegible] are covered first b[illegible] themselves or by the [illegible] or else by the As[illegible] approach to our Poor-law administration. Thus, out of 271 patients treated in 1901 at the Zürich sanatorium of Wald 178 paid for their own board, 40 were paid for by the benefit societies to which they belonged, 33 were recipients of private charity, and only 20 were sent by the Assistance Publique. As for the result of such treatment figures are given only in regard to 2954 cases treated from 1899 to 1901 and divided into three stages or categories according to their condition on admission. Among the patients in the first stage 96 per cent. improved, 3 per cent. remained stationary, and 1 per cent. died. Of the second stage 84 improved, 12 did not, and four died per 100 patients. Out of the patients in the third stage only 58·2 improved, 39·5 remained as they were, and 2·3 per cent. died. Those who were restored to their full working capacity amounted to 85·2 per cent. among the patients in the first stage, 49·5 for the second stage, and 10·9 for the third stage.

To go to another small country, Dr. Knud Faber of the University of Copenhagen has urged that tuberculosis follows much the same course as leprosy and necessitates similar precautions. The departmental medical officer of Färöe, Dr. Boeg, was able to obtain the history of 342 patients suffering from tuberculosis who lived simple isolated lives in the archipelago and whom he had watched for 20 years. No less than 77 per cent. of these cases seemed due to infection as the patients had frequently associated with others suffering from the disease; in 66 per cent. they lived in the same house; in 40 per cent. one of the parents and in 47 per cent. a brother or a sister suffered from tuberculosis. The necessity of special hospitals is generally recognised in Denmark and the State has given grants in aid of the benefit societies that seek to build such hospitals or sanatoriums. The law of April 12th, 1892, sanctions the giving by the State of a subsidy of 2*s.* 6*d.* per day per patient to benefit societies which place their funds under the control of the State. There are now 1228 such funds or societies with a membership of close upon 400,000 persons. In the ordinary hospitals of Copenhagen it was found that 20 per cent. of the patients were suffering from tuberculosis of the lungs and this led to the opening, at a cost of 700,000 crowns, of a sanatorium in the forest of Bosera containing 144 beds. In the island of Bornholm and elsewhere there are sanatoriums for scrofulous and other diseases and there are private sanatoriums, one of 170 beds, outside, but near to, Copenhagen for the treatment of tuberculosis. So much has been done that in the capital of Denmark the mortality from this disease has been reduced from 3·1 to 1·8 per 1000 inhabitants.

It is, however, in Norway that the most stringent measures have been taken implying absolute belief in the infectious nature of phthisis. Nevertheless the legislation bearing on this question is of too recent a date to enable any opinion to be formed as to the result; also its object is to prevent the spread of the disease rather than to cure the patients. The whole question is governed by a special law which bears the date May 8th, 1900. This law renders the notification of cases of tuberculosis obligatory whenever the sputum is likel[illegible] Then prophylactic measures, [illegible] the case, are imposed. [illegible] in case of death or of removal. No boarder can be taken to lodge with a family where there is a case of tuberculosis. No person suffering from this disease is allowed to prepare, to sell, or to have anything to do with articles of food; nor may such engage themselves as nurses or domestics in private families. Finally, any patient who has not the means of nursing himself properly at home or who is neglectful and does not show himself willing to carry out the prophylactic instructions given to him can be seized and conveyed by force to a hospital.

In Holland the State aids those who seek to establish sanatoriums. In Belgium it has been seen that the authorities governing the province of Liège have made a notable effort at Borgoumont, while both France and Italy have only reached the stage of discussing whether or not the State should take the initiative and build sanatoriums for this purpose. Yet the Assistance Publique of Paris has [illegible]shed a sanatorium at Angicourt and when M. Millerand [illegible]inister of the Posts and Telegraphs he sought to [illegible] another sanatorium for the postal servants. Still, [illegible]chemes find very strong opponents, Dr. A. Robin [illegible] placed himself at the head of the opposition. This eminent physician maintains that a certain number of patients are admitted into sanatoriums who are not really infected with tuberculosis and this falsifies the results.

terms "the long tube" as a means of diagnosis (second edition, p. 319). He rightly describes the part as a *loop* provided with an extensive mesocolon, in some examples amounting to from 18 to 20 inches in length and capable of touching the gall-bladder, the cæcum, or the umbilicus. The importance in everyday practice of keeping in the mind a correct conception of this part of the intestine is obvious and I think the practitioner will be greatly aided if he remembers the sigmoid cavities of the radius and ulna and why they are so called.

THE ROYAL ORTHOPÆDIC HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I am instructed by the committee of the Royal Orthopædic Hospital to inform you, with reference to the circular issued by the secretary of the City Orthopædic Hospital dated Jan. 14th, 1904, that the statement contained in that circular to the effect that the Royal Orthopædic Hospital has ceased to exist is entirely untrue. As you have been informed, the Royal Orthopædic Hospital is amalgamated with the National Orthopædic Hospital under the sanction and with the strong approval of King Edward's Hospital Fund for London.

Arrangements have been made for the erection of a new building in which the work of the combined institution will be carried on under one management. In the meantime the work of the Royal Orthopædic Hospital is being carried on in temporary premises at 55, Bolsover-street, W., where both in-patients and out-patients continue to be received. So far as my committee can learn, not one patient of the Royal Orthopædic Hospital has gone to the City Orthopædic Hospital and the suggestion that the amalgamation has in any way increased the work of the City Orthopædic Hospital is without foundation.—I am, Sirs, yours faithfully,

TATE S. MANSFORD, Secretary.
Royal Orthopædic Hospital, 55, Bolsover-street, W., June 27th, 1904.

THE GOVERNMENT OF INDIA AND THE ROYAL ARMY MEDICAL CORPS.

To the Editors of THE LANCET.

SIRS,—Paragraph 429 of the Regulations for the Allowances of the Army, 1903, reads as follows:—"Married officers when necessarily employed on duty with troops on board ship will be entitled to free accommodation for their wives and children, if permitted to accompany them." With regard to India, to which place a very large percentage of the officers of the Royal Army Medical Corps go, this regulation is got over in the following manner. About last January a letter was received by the Director-General of the Army Medical Service from the War Office directing that in future only bachelor officers were to be detailed for duty with troops for India. This must have been done at the instance of the Indian Government. A married officer of the Royal Army Medical Corps with three children thus loses at least £150 over each voyage to or from India, as shown by the following table:—

Per P. and O. steamboat.		Per hired transport.				
	£			£	s.	d.
Self	52	... ...			nil.	
Wife	52	... ... 20 days' messing at	5s. 6d.	5	10	0
Child 8 years old	26	... ... " "	4s. 0d.	4	0	0
" 5 "	26	... ... " "	2s. 6d.	2	10	0
" 4 "	26	... ... " "	2s. 6d.	2	10	0
Nurse (2nd class)	32	... ... " "	2s. 6d.	2	10	0
Total ...	£214		Total ...	£17	0	0

Deducting from the £214 the £17 for messing on board the transport and the £47 10s. received from the Government the above-mentioned officer loses quite £150, taking into account the lesser cost of extras on board the transport. As a medical officer will in ordinary course perform three journeys to and from India in seven years he would lose at least £450 in this short period. Moreover, when he reaches India he probably has at least one expensive move in front of him in his new command.

Veterinary officers, in accordance with paragraph 426 (*b*) of the Allowance Regulations are always entitled to free passage for their wives and families whether travelling with or without troops. As may be seen, this invidious distinction is a cruel hardship on the medical officer. Regimental officers, as a rule, travel with troops and accordingly are allowed free passages for their families.

The Government of India has recently (May 7th, 1904) ruled that an officer of the Royal Army Medical Corps transferred to a station carrying a higher rate of charge allowance must be viewed as transferred to a more lucrative appointment for the purpose of paragraph 103 (2) of the Army Regulations of India, vol. x. According to this ruling a medical officer landing at Bombay and ordered to Quetta as a specialist at Rs. 50 a month may be put to the expense of Rs. 1000 over the journey of his family and very likely would regret the day he became a specialist. The same thing happens in the case of an officer transferred, say, to an appointment with an increase of charge pay of Rs. 60 a month, the expense of the journey possibly amounting to much more than the total sum received over the larger rate of charge pay. If, say, an officer moves from Darjeeling to Dinapore to assume charge of a station hospital with an extra Rs. 60 per month charge pay he is never likely to be able to recoup himself for the great expense of the journey of his family. If these moves occurred at the officer's own wish one might possibly be able to understand it. *In fact, the senior or specialist officer will often prefer* to remain in the lower-paid appointment, but unfortunately will not always be allowed to.

The Government of India recently raised the pay of certain of the ranks of the Royal Army Medical Corps after great pressure but by the above new rules it will more than recoup itself for its great generosity.

I am, Sirs, yours faithfully,
QUATUOR MARIA.

THE ROYAL HOSPITAL FOR INCURABLES AND THE DISPUTED LEGACY.

To the Editors of THE LANCET.

SIRS,—Your issue of Dec. 5th, 1903, p. 1611, contains a paragraph headed "Inaccurately Worded Legacies." In this paragraph particulars are given of a then recent decision by a judge of first instance in the Chancery Division to the effect that the British Home and Hospital for Incurables at Streatham was entitled to receive a legacy expressed by a testatrix to be given to "The Royal Home for Incurables, Streatham," and which had then already been paid to the Royal Hospital for Incurables at Putney by the testatrix's executors.

The board of the Royal Hospital for Incurables desire us to acquaint your readers with the following facts. First, that the decision in question was in the month of March reversed by an unanimous decision of the Court of Appeal, and the institution which they represent was held to be entitled to the legacy; and, secondly, that besides the evidence of the donor's intention, legally admissible, there existed in the executors' control additional evidence, not legally admissible, but leaving no moral doubt as to the institution which it was the testatrix's intention to benefit. It has recently come to the knowledge of the board of the Royal Hospital for Incurables that the paragraph from your paper has been reprinted and circulated. As this states the facts only up to a certain point the board think it desirable that the additional facts above detailed should be before your readers and hence we would ask you to permit the insertion of this letter in your next issue.

We are, Sirs, yours faithfully,
FARRER AND CO.
Lincoln's Inn-fields, London, W.C., June 27th, 1904.

FIFTY YEARS OF PAROCHIAL MEDICAL SERVICE.—Mr. Robert Girvan, L.R.C.S. Edin., who was appointed to his present position as medical officer to the Parish council of Maybole, N.B., on June 7th, 1854, has been congratulated by the chairman on behalf of the council on the occasion of his jubilee, the chairman also expressing the appreciation of the council of the thorough and conscientious manner in which he had always performed his duties. Mr. Girvan served for 35 years in the 2nd Volunteer Battalion Royal Scots Fusiliers and retired with the rank of Surgeon-Lieutenant-Colonel, being awarded the volunteer decoration. It is entirely owing to Mr. Girvan's retiring disposition that no public ceremony has taken place to mark his 50 years of parochial service.

soap-boilers and guano manufacturers, be placed under certain restrictions so that they should not become a nuisance and a danger to the general public and should be made to carry on tl [illegible] inhabited houses. T [illegible] is unique. Nothing [illegible] and [illegible] ther- [illegible] this [illegible] the cause of public health.

*** We have received a letter from Mr. P. Harold Jones denying that a dying patient has been at any time removed from Farleigh House and stating that "the number of beds in Farleigh House and Lymington House are not 49 but 32." The number of beds would seem to have been altered since the inspection of the homes by our Special Commissioner, to whom the late Mr. J. J. Jones supplied full particulars. Mr. Harold Jones is quite right in believing that our articles are not "actuated by any personal spite but solely by public motives," and no good purpose would be served by the publication of his letter. Our readers will see by an annotation published on another page that the suggested discussion of the matter by the Congress of the Royal Institute of Public Health at Folkestone has been adopted, and we can only reiterate our Special Commissioner's hope that such a discussion will have tangible results in regard to the public health.—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

A Water Grievance in Bombay City.—The Continued High Mortality from Plague throughout India.

CERTAIN parts of Bombay city periodically suffer from a bad water-supply. Of the three lakes as sources for the requirements of the city the "Vehur" and "Tausa" are generally good but the smaller "Tulsi," which largely supplies the European quarter of Malabar Hill, seems to be annually subject to contamination. Lately the water has been so complained about that even a bath in it is said to be unpleasant and the stench given off while watering a garden is described as unbearable. When the level of the lake gets low it is said that liquid filth is carried off by the main. The filter beds are not ready and the project for connecting the mains with the other supplies has not been commenced.

The mortality from plague throughout India is improving but for the week ending May 28th there were 20,484 deaths. The Punjab recorded 18,086, as against 24,853 for the previous seven days; Bombay Presidency 798, as against 1086; United Provinces 652, as against 1069; Bengal 200, as against 215; Rajputana 166, as against 195; Kashmir 73, as against 74; Bombay city 129, as against 208; Calcutta 90, as against 134; and Karachi 62, as against 77. Since the above figures were issued the disease has further declined in Calcutta and in Bombay city.

I have drawn attention at different times to the absence of figures for Poona amongst the weekly published returns. It appears that this city has been somewhat severely attacked, over 3000 deaths having occurred since last September. Although this mortality is not so great as in previous outbreaks it compares unfavourably with other places, 1 in 40 of the population having fallen a victim to plague. From 1896 to the present time Poona has probably lost a larger proportion of its inhabitants than any other city.

June 10th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Medical Benevolent Society.

THE annual meeting of this society has recently been held, Mr. M. A. Messiter, the President, being in the chair. Dr. Edward Malins was appointed President, Dr. A. S. Underhill (West Bromwich) President-elect, and Mr. W. Flewitt (Bir- [illegible] W. Greene (Stratford-on- [illegible] ensuing year. The report [illegible] amount to £15,688 4*s.* 6*d.* [illegible] annuitants were on the books at the commencement of [illegible] e year. One died during the year and five new annuitants [illegible] re added to the list. The annual value of the grants ranged from £20 to £40 and the sum expended in this way was £755. The directors regretted that owing to the large number of annuitants they were unable to send them any donation at Christmas, as has been the case during the last few years. The total number of "benefit" members of the society at the end of the year was 411.

Dental Hospital.

A special appeal has now been issued to the public for the funds requisite for the provision of a very much needed new building for the Dental Hospital. The existing institution is the only one of its kind in the Midlands, there being no others nearer than London, Manchester, and Liverpool, and receives patients from a very large area. It is therefore only reasonable to hope that subscriptions may be rapidly forthcoming, seeing that the amount asked for is a very moderate sum, £8500 for building and £1500 for equipment. When the hospital was removed to its present position in the centre of the city and close to the site for the new building the number of patients received during the year was 5515. This was in 1882, and in 1902 the number was about double—viz., 11,112. A very large amount of conservative work is done as will be seen by the fact that in 1902 no less than 3046 teeth were saved by stopping, fixing crowns, &c. I am glad to see that the first list of subscriptions, which is appended to the appeal, amounts to about £3500 and I sincerely hope that a most deserving institution will soon obtain the funds required for its proper housing.

Open-air Treatment of Pulmonary Tuberculosis.

The board of guardians of the Aston union has been considering the advisability of providing some accommodation for treatment of this kind and has been inquiring into the success of the experiment which has already been made in this direction by the Birmingham board. The result of its inquiries has not been very enco [illegible] Birmingham board has erect [illegible] corrugated iron, lath, and plast [illegible] six patients. This only cost [illegible] expenditure has scarcely been justified by the results. It appears that the patients for whom the shelter was designed will not have anything to do with it save as a last resort and when their cases are so advanced as to render the success of the treatment very doubtful. And when they do enter the shelter they soon weary of the rigorous treatment and leave before they have had time to receive any real benefit. The shelter seldom contains the modest number of six for which it was designed. The result of these inquiries will probably be that the Aston board will refrain from undertaking any expenditure in this direction.

Health of Coventry.

The report of Dr. E. N. Snell, medical officer of health, shows a low rate of infantile mortality during 1903, the figure being 114 per 1000 births. The average rate for the past ten years has been 152. Only once previously was a lower figure recorded and that was in 1902 when there were 107 per 1000 births. The decline in numbers was due to the comparatively small prevalence of epidemic diarrhœa and the increase on the previous year was caused by deaths from measles and whooping-cough. The zymotic death-rate was 2·06 per 1000, the average for the previous ten years having been 1·9. The death-rate for scarlet fever, enteric fever, whooping-cough, and diarrhœa was below that for the rest of the country but the death-rate from measles and diphtheria, and especially from the former, was greatly in excess. The very extensive epidemic of measles with its heavy toll of 57 deaths was mainly instrumental in raising the zymotic death-rate for the year above that for the country generally. With regard to small-pox, the report states that it is now 30 years and more since the city was visited with so extensive an epidemic. In 1871, 166 deaths were due to it and in the following year there were 57 deaths. Since those years only two deaths were registered as due to this cause— [illegible] of the disease [illegible] r and in the [illegible] to assume alarming proportions. Dr. Snell points out that no epidemic of this disease need ever be considered as alarming if people would take the natural precaution of being revaccinated but in view of the neglect of such precaution an epidemic may easily become alarming when it is considered that not merely the life and death of citizens are at stake but also the prosperity of the city which might be depressed for a number of years as the result of a serious epidemic. Dr. Snell gives a number of details of the cases which occurred and thus shows that the infection was introduced afresh on several distinct occasions, and then through the wilful or negligent refusal to take advantage of the preventive means of vaccination amongst those who were exposed to the direct risk of infection the disease went on its way through entire families or amongst neighbours who came in contact with one another as intimately as relatives would do.

North Staffordshire Small-pox Hospital.

At a recent meeting of the board of this institution, held at Hanley, Dr. C. H. Phillips, the medical officer, reported that 47 cases had been admitted to the hospital during the first quarter of the year, including 15 from Newcastle-under-Lyme and 29 from Leek. There had been 21 patients discharged, two had died, and 24 remained under treatment. Seven other patients were announced from Leek. He strongly advocated the provision of an administrative block, as the staff was in danger through having to occupy bedrooms in the wards continuously. The board considered modified plans for the provision of permanent buildings at the hospital and ultimately adopted the original plans with slight alterations, the estimated cost of the buildings being £5900.

Margarine Prosecution.

The stipendiary magistrate for the Potteries had recently before him at Fenton a number of cases in which traders were charged with offences under the Sale of Food and Drugs and the Margarine Acts. John Richard Midgley of Leeds was summoned for selling as butter an article which was actually margarine containing only 3½ per cent. of butter and also with dealing with margarine wholesale without having the package in which it was inclosed branded. He was further charged with selling as Cheddar cheese an article which was really margarine cheese and also with selling margarine cheese in an open package which was not properly branded with the name of the article. After a lengthy hearing the stipendiary said that he was only sorry that he could not send the defendant to gaol. A more deliberate fraud he never had evidence of. The obtaining of money by this means was the worst and meanest kind of false pretence. It affected the poorest people and often ruined the retailer. He could not send the offender to prison and therefore he fined him the full penalty of £20 and costs in each of the six cases—£141 in all. Other cases arising out of this one were tried but as it appeared that the defendants had been more or less deceived by Midgley they were let off either with lighter fines or without fines at all.

General Hospital.

At the meeting of the committee held on June 24th Dr. T. Sydney Short was elected to the honorary physiciancy rendered vacant by the resignation of Dr. E. Rickards, to which I alluded in my last letter. As Dr. Short has held the position of assistant physician for a number of years a vacancy now arises in that post. As this has been fully anticipated two candidates are already in the field—viz., Dr. S. Herbert Perry who is one of the casualty physicians to the hospital, and Dr. A. Stanley Barnes who is pathologist to the Queen's Hospital. Both of these gentlemen are past students of the Birmingham School and are well known in the city.

June 28th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The University of Manchester.

IT was announced on June 27th that the Royal Assent had been given to the Victoria University of Manchester Act, 1904. By this measure the Owens College becomes incorporated in the University and now ceases to exist "as a separate corporation." All the property (real and personal) and all the rights, powers, and privileges of the College are invested in the University "and applied to the objects and purposes for which the University is incorporated." The arms of the College are adopted by the University but the buildings now existing will continue to be known by the old name of "the Owens College," while the professors and other members of the teaching staff will hold "as nearly as is practicable the same offices and places" in the University as they have held in the College. The rights of the College as to the appointment or nomination of members of governing bodies of educational, charitable, or other institutions are transferred to the Council of the University, and any such rights of the Senate of the College pass over to the Senate of the University; and all bequests, gifts, or trusts in favour of the College are to have effect as if the University were named and not the College. The Duke of Devonshire now becomes the President of the University of Manchester and is empowered to preside at meetings and to confer degrees in the absence of the Chancellor (Earl Spencer).

The New Royal Infirmary.

A meeting of the board of management of the Manchester Royal Infirmary was held yesterday under the chairmanship of Mr. W. Cobbett. It appears that the building committee has examined the plans for the Stanley-grove building with a view to some modification and the architects have made certain suggestions to the committee which have been approved and embodied in a report. This report has been approved by the board and will be considered by the medical board. The changes suggested have not yet been made public but they are intended to reduce the cost without diminishing the accommodation of the new infirmary or affecting its efficiency. The Stanley-grove site is to be cleared within four months.

Dangers of Electricity.

As long as it is under control we all welcome the powerful agent that science has made available by putting electricity into harness. But the conditions necessary for its safe use are so delicate and therefore so easily disturbed that the greatest possible care will always have to be taken if accidents are to be avoided. On June 25th an illustration of this occurred at the Newland collieries, Normanton. Three men were working with an electric cutter "when an electric coil fused and an explosion occurred." They were all seriously burned and removed to the Clayton Hospital, Wakefield, in a critical condition. One would think that the electrocutions from "live rails" that we read of from time to time might be, and therefore ought to be, prevented by some mode of protection and that these rails ought not to be left open to catch trespassers who, even if they trespass, will scarcely be thought worthy of death. Then, too, there are very many people who live in dread, not altogether foolish, from the increasing dangers of the streets. They fear the network of death-dealing wires hanging over their heads like the sword of Damocles, to say nothing of the electric cars themselves which, as a rule, certainly keep to their own tracks. It is perhaps not easy to see how all these dangers are to be avoided but it is a matter to which men of science might well turn their attention with some earnestness.

Cheshire Hospital Scheme.

On June 24th at a meeting of the Mid-Cheshire joint hospital committee it was stated that in order to avoid delay in the erection of the joint hospital the Local Government Board sanctioned the borrowing of £13,885 to cover the cost of the building. The district includes the areas of Northwich rural and urban districts and the urban districts also of Winsford and Middlewich. The Cheshire county council is to borrow the money which is to be repaid by the joint authority minus the amount contributed by the council.

The Owens College Extensions.

The late Dr. Schunk, who was well known as a scientific chemist, left a large sum to the Owens College for the promotion of research and also his extensive and valuable library. As the result of this bequest the Schunk Laboratory will be opened early next month by Dr. W. H. Perkin, sen. It comprises a basement and a large laboratory on the first floor, with a balance room attached, and a library on the top storey which is to be finished most artistically. The laboratory proper is a spacious apartment overlooking Burlington-street. An extension of the inorganic laboratories and the metallurgical laboratory was decided upon some time since in honour of the centenary of the announcement of Dalton's atomic theory. During the centenary celebrations Professor van 'tHoff unveiled a memorial stone in the Dalton Laboratory. Although the

development of ch
has extended into
medical student its progress will always be watched with sympathetic interest by the medical profession and with the feeling, moreover, that at any time new powers may be revealed that will strengthen the hands of those whose work it is to combat disease and suffering.

Port Sanitary Authority.

It is difficult for those not specially interested in the docks and the shipping to feel that Manchester is a seaport notwithstanding the fact that the annual report just issued by the medical officer, Dr. A. M. N. Pringle, is the seventh since the formation of the port sanitary authority in 1897. As the trade of the port gradually increases so do the cases of sickness that have to be investigated. In 1897 there were 16, in 1898 65, and in 1901 89, having gradually increased, but in 1902 there was a considerable rise to 144 while last year there were 124 cases. As Dr. Pringle says, with this progressive increase in the number of cases there is increasing liability to the importation of infectious disease not only from this cause but also from the increased area from which infection may come. He considers that the time is opportune "for the consideration of the question of international notification of infectious disease." At present the daily papers supply all the information available. He would have at least plague, small-pox, and cholera notified internationally. Last year there was only one case of small-pox, so that the ship-imported small-pox cannot rival that carried about the country by tramps. There were 2977 inspections in 1903 as compared with 2965 in 1902. Of the vessels inspected 1311 were British steamships, 721 were British sailing ships, and 39 were foreign sailing ships.

June 28th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

British Medical Association.

AT the annual meeting of the Worcestershire and Herefordshire branch of the British Medical Association held at Hereford on June 24th Dr. J. B. Fitzsimons of Hereford was elected president and Mr. T. Preston Gostling of Worcester president-elect. Dr. George W. Crowe of Worcester, who is the joint representative on the council of the Association of this branch and the Gloucestershire branch, was re-elected secretary, an office which he has held for many years. In his presidential address Dr. Fitzsimons dealt with the influence of hospital isolation upon scarlet fever in the city of Hereford. It appears that cases of scarlet fever have been notified in Hereford for the past 20 years and compulsorily so for 17 years. The isolation hospital has been available for ten years. In the ten years prior to the establishment of the hospital there was a yearly average of 1·44 per 1000 of the population attacked with scarlet fever with a case mortality of 4·1 per cent. and a death-rate of 0 06 per 1000 of the population. In the first five years after the opening of the hospital a yearly average of 5·8 per 1000 were attacked, 33 per cent. of these were removed to the hospital, there was a case mortality for the whole town of 4·1 per cent., and a death-rate of 0·24 per 1000. In the second five years, when 68 per cent. of the cases reported were isolated in the hospital, there was an attack rate of 1·8 per 1000, a case mortality of 1 per cent., and a death-rate of 0·016 per 1000 of the entire population. In the first five hospital years there was an average yearly death-rate among children under five years of age of 1·7 per 100 of the children living at that age group, while in the second five hospital years there were no deaths recorded of children below five years of age. Dr. Fitzsimons, who is the medical superintendent of the Hereford Isolation Hospital, stated that he discharged most patients at the end of six weeks from the commencement of the disease and he had only had two "return" cases. He thought that in certain instances this period of detention might be shortened. In the discussion which followed the reading of the address several speakers emphasised the important part played by nasal and aural discharges in spreading the infection.

The Midwives Act.

The medical officer of health of Cardiff (Dr. E. Walford) has given a great deal of careful thought to the administration of the Midwives Act. The borough council as the local who was appointed executive officer, has upon more than one occasion suggested the establishment in Cardiff of a training centre for midwives and it appears to be likely that his suggestion will be carried out. The council of the Cardiff University College has expressed its willingness to establish a course of lectures for midwives provided certain financial assistance can be relied upon. The technical instruction committee of the borough of Cardiff has promised to contribute £50 yearly towards the scheme and the education committee of the Glamorgan county council has recently been approached on the subject by a deputation from the Cardiff division of the British Medical Association. Dr. E. J. Maclean told the committee that of the 40,000 children born annually in the six southern counties of Wales 30,000 were born in Glamorganshire and he said it was estimated that 19,500 labours in that county were attended by 1000 women acting as midwives. He further pointed out that the accidents of childbirth and the number of cases of puerperal septic diseases were very considerably higher in the county of Glamorgan than in other parts of England and Wales.

Bangor University College.

It is announced that £42,000 have already been subscribed towards the fund for providing permanent buildings at Bangor for the University of Wales. The total amount required is estimated at £175,000.

West Wales Sanatorium.

As the result of a conference between representatives of the county councils of Carmarthen, Cardigan, and Pembroke and Sir John Williams and other members of the West Wales branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis a recommendation is to be made to the county councils named to contribute an aggregate sum of £3000 towards the cost of erecting a sanatorium near Llanybyther in Carmarthenshire.

New Waterworks at Street.

The completion of waterworks for the supply of the town of Street in Somerset was formally recognised on June 18th. The town has a population of about 4000 persons and the cost of the undertaking was £25,000. Water is brought from the Mendip Hills and is stored in a low level and a high level reservoir, being raised to the latter by suitable pumping machinery.

A Small-pox Hospital for Kingswood.

At a meeting of the Kingswood (Bristol) urban council held on June 20th it was reported that a case of small-pox had occurred in the district. The council decided on the immediate erection of an iron hospital containing six beds for small-pox cases at an estimated cost of about £400.

Medical Cricket Match at Bristol.

The annual cricket match between members of the staff and students of the Royal Infirmary and General Hospital was played at the Gloucestershire county cricket ground, Bristol, on June 23rd and resulted in a win for the former team by 59 runs.

June 27th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Alcoholism and Insanity.

IN submitting his annual report at the meeting of the directors of Dundee Royal Lunatic Asylum Dr. W. Tuach stated that in 20 cases admitted to the Royal Asylum it was demonstrated that the patients were hereditarily predisposed to mental disease, and next to heredity as a causative agent had to be put intemperance in drink, this having been shown to be the exciting cause in ten cases. To those whose work lay among the insane the rôle which intemperance in drink as an exciting cause of mental disease played in the filling of asylums was becoming more and more evident each year. The numbers admitted from this cause were increasing steadily from year to year. Drink was a black spot in our social life. It was very difficult to say whether a man was insane because he drank to excess or whether he drank because he was insane.

An Aberdeen Physician in the Far East.

The Hong-Kong papers contain eulogistic notices of the had been proved in animals Professor Jacob proceeded to make use of it in the human subject. The idea of local treatment of bronchial and pulmonary diseases was, he said, of ancient date, but inhalation was the only means that had hitherto been found practicable for the administration of medicines with this object and it was known that fluids administered in this manner did not make their way to the lungs, whereas when injected they were brought into direct contact with the diseased part. The procedure was not at all complicated and was quite within the power of any medical man acquainted with laryngoscopy. The larynx and trachea were first anæsthetised with cocaine and anæsthesin, after which a small caoutchouc tube was passed through the mouth, the larynx, and the trachea. The patient was then placed so that his head was in a reclining position and some grammes of the solution were injected with a small syringe. Injections of tuberculin and creasote caused disappearance of the tubercle bacilli in from four to eight weeks. A febrile reaction occurred after the use of tuberculin and Professor Jacob was of opinion that the injection method, apart from its therapeutical advantages, might also be used for the tuberculin test to ascertain in doubtful cases whether a case was one of tuberculosis or not and which of the lungs was affected. Up to the present time five patients had been treated by injection; the results were described as satisfactory so that the treatment was to be continued on a larger scale. The discussion of the paper was adjourned to the next meeting of the society.

Professor Koch.

Professor Robert Koch, after an absence of one and a half years, returned to Berlin on June 11th. The rumour that he had intended to leave Berlin altogether and to enter the British colonial service was unfounded, as I have already stated in THE LANCET of Feb. 27th, 1904, p. 617. It will be remembered that he went to British South Africa at the request of the colonial authorities for the purpose of carrying out investigations on Texas fever and on horse sickness which are so prevalent in that part of the world. The medical profession will be glad to learn that Professor Koch's health is as good as ever and that he was able at once to resume his duties as chief of the Royal Institution for Infectious Disease. Since his return he has been interviewed by a medical man belonging to the staff of the *Lokal Anzeiger*, an important Berlin daily paper, and he is said to be very well satisfied with the results of his stay in South Africa. He told his interviewer that his work lay almost exclusively in Rhodesia and that he had discovered that the cattle suffered neither from rinderpest nor from Texas fever but from a specific disease which had long been prevalent on the East African coast and had probably been imported into Rhodesia by cattle brought from the coast. Professor Koch said that he had recognised the disease seven years ago on the coast of German East Africa, that it had been termed by him "coast fever," and that he had succeeded in finding a method of immunising cattle against it. He had also made an investigation of the so-called "horse sickness," from which about 90 per cent. of the horses died in some districts and which had hitherto resisted all curative and immunising methods. Professor Koch is said to have devised means of immunisation which worked satisfactorily in the laboratory but must, of course, be tried in cases of natural infection; the laboratory experiments will be continued in Berlin. It would be of interest to know Professor Koch's opinion as to Professor Behring's theory on the subject of tuberculosis. Professor Behring's views were published during Professor Koch's absence and I learn from a trustworthy source that the latter has no intention of renewing the discussion because his belief in the essential difference between bovine and human tuberculosis remains unaltered.

Poisoning by Acetone.

Dr. Cossmann, surgeon to the Duisburg Hospital, writing to the *Munchener Medicinische Wochenschrift*, reports a case of poisoning by acetone which had been used as a solvent of celluloid in the making of a surgical appliance. The patient suffered from tuberculosis of the hip-joint and a sort of splint had been applied consisting in part of gauze bandages moistened with the acetone solution. A few hours later the patient passed into a state resembling diabetic coma, associated with somnolence, difficult respiration, and irregular pulse. Most of the symptoms disappeared after the removal of the splint and the use of artificial respiration, hot compresses, and injections of saline solution, but the somnolence and unconsciousness continued for about 24 hours. The urine and the vomited matter contained acetone and there was a strong smell of that substance in the breath. Obviously the acetone must have been absorbed through the skin. Attempts to poison a dog by applying an acetone dressing were, however, unsuccessful.

June 28th.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The order of the first examination at Cambridge in tropical medicine and hygiene to be held in August next is as follows: Tuesday, August 9th, from 9 A.M. to 12 noon, in the New Medical Buildings (Cambridge), paper [illegible]eriology, and from 2 to 6 P.M., in the Nc [illegible] oral and practical; Wednesday, August 10th, from 9 A.M. to 12 noon, in the New Medical Buildings, paper in medicine and hygiene, and from 2 to 6 P.M., in the New Medical Buildings, oral and practical; and on Thursday, August 11th, beginning at 3 P.M. punctually, in the wards of the Seamen's Hospital Society, Branch Hospital, Royal Albert Dock, London, E., clinical medicine and surgery.—The following degrees were conferred on June 21st:—

Bachelor of Medicine.—J. E. Pellow, St. John's; E. A. A. Beck, Clare; W. H. Hills, Pembroke; J. S. Cooper, Jesus; G. S. Colt and J. B. Dunlop, Sidney-Sussex; and A. R. Brailey, Downing.

Bachelor of Surgery.—A. W. D. Coventon, W. L Cripps, H. M. Davies, E. Harrison, and R. H. Robbins, Trinity; D. H. Fraser, Caius; J. S. Cooper, J. Goss, and B. H. Stewart, Jesus; R. A. Clapham and R. O. Lee, Emmanuel; and G. H. Colt and J. B. Dunlop, Sidney-Sussex.

During the year thus closed the numbers of medical and surgical degrees conferred are given as follows: B.C., 80; M.B., 72; M.C., 3; and M.D., 19.

At the third examination for medical and surgical degrees, Easter term, the following candidates were successful:—

Part II. Surgery, Midwifery, and Medicine.—A. E. Barclay, M.A., Christ's; H. J. D. Birkett, B.A., Trinity; E. M. Brown, B.A., and S. Child, B.A., Pembroke; R. A. Clapham, B.A., Emmanuel; G. H. Colt, B.A., Sidney Sussex; A. W. D. Coventon, B.A., W. L. Cripps, B.A., H. M. Davies, B.A., and R. G. Elwell, B.A., Trinity; H. Falk, B.A., King's; G. R. Footner, B.A., Pembroke; D. H. Fraser, B.A., Caius; J. Goss, B.A., Jesus; C. F. Hadfield, M.A., and Everard Harrison, B.A., Trinity; W. Hastings, B.A., Christ's; T. G. M. Hine, M.A., and H. F. Horne, B.A., King's; W. E. Hume, B.A., Pembroke; K. H. A. Kellie, B.A., Caius; J. Lambert, B.A., Downing; R. O. Lee, B.A., Emmanuel; T. C. Lucas, B.A., Clare; S. M. Mackenzie, B.A., Trinity; C. W. P. Moffatt, B.A., Clare; W. M. Mollison, B.A., King's; A. R. Moore, B.A., Caius; R. F. Moore, B.A., Christ's; W. V. Naish, M.A., Emmanuel; R. G. Nothwanger, M.A., and C. T. MacL. Plowright, B.A., St. John's; C. A. W. Pope, B.A., H. Rischbeith, M.A., and R. H. Robbins, B.A., Trinity; B. H. Stewart, B A., Jesus; C. Stiebel, Trinity Hall; G. A. Ticehurst, B.A., St. John's; R. E. Whitting, B.A., King's; and R. A. Worthington, B.A., Clare.

TRINITY COLLEGE, DUBLIN.—At examinations held at Trinity term the following candidates were successful:—

PREVIOUS MEDICAL EXAMINATION.

Anatomy and Institutes [illegible] is R. Coppinger, Robert E. [illegible] ton, John W. Tomb, Charle [illegible] G. S. Gregg, Gustav W. Thc [illegible] s G. Sherlock, Reginald Holmes, Thomas L. de Courcey, Henry D. Drennan, Dudley S. Torrens, Edward C. Stoney, Herbert J. Wright, Malcolm K. Acheson, William Hutchison, Robert B. Jackson, George E. G. Vickery, Francis Casement, Francis W. H. Bigley, Ernest Jameson, Ernest D. Caddell, Edward Evans, and William A. Nicholson.

Physics and Chemistry.—Richard P. Hadden, Charles F. F. Davies, William R. G. Atkins, Ernest C. Lambkin, Dixie P. Clement, Johannes C. Pretorius, Robert V. Dixon, James F. Clarke, Douglas M. Moffatt, Robert G. Orr, William E. Hopkins, Frederick A. Anderson, Gerald Mecredy, Henry H. Ormsby, Samuel F. A. Charles, Norman Jewell, Charles W. Laird, James D. Murphy, John L. Phibbs, Albert V. Richardson, Harold S. Sugars, and Richard J. Attridge.

Botany and Zoology.—Ralph T. Brooks, Arthur H. Land, Ernest C. Lambkin, Charles F. F. Davies, Richard P. Hadden, Albert J. Stals, William E. Hopkins, Charles W. Laird, Charles G. S. Baronsfeather, Henry R. Kenny, Johannes C. Pretorius, Dixie P. Clement, Frank N. Smartt, Robert E. T. Tatlow, Douglas M. Moffatt, John L. Phibbs, William R. G. Atkins, Thomas P. S. Eves, William Knapp, George H. Stack, James Brereton-Barry, Gordon A. Jackson, Norman Jewell, Alfred H. Smith, Alexander S. Winder, James Beckett, Derrick W. Knight, John T. M'Donnell, Kenneth Smith, Cecil Grene, and Frederick C. Newland.

DIPLOMA IN PUBLIC HEALTH.

Parts I. and II.—Alexander H. Marks.

ALLEGED IMPROPER TREATMENT OF CHILDREN UNDER THE POOR-LAW.—At a recent meeting of the Fylde board of guardians Miss Johnson, a new member of the board, asked for an inquiry respecting certain children attached to the union who are being sent to school while [illegible] also [illegible] rom [illegible] It is [illegible] nce [illegible] hile [illegible] iiry [illegible] on- [illegible] en. [illegible]

Royal Army Medical Corps Militia.—Colonel Sir J. R. A. Clark, Bart., C.B., and the officers of the Royal Army Medical Corps Militia dined together on June 21st at the Trocadéro Restaurant, London. The company included some distinguished guests and to the right of the chair were seated Director-General Sir W. Taylor, K.C.B., Major M. O'Connor, Colonel A. T. Sloggett, C.M.G., Captain A. H. Benson, Colonel H. B. Williams, Major T. McCulloch, Captain E. W. Bartholomew, and Lieutenant-Colonel E. M. Wilson, C.B., C.M.G. To the left of the chair were seated Sir E. Cooper Perry, Captain J. Tracy Simpson, Colonel H. E. R. James, Lieutenant J. C. Furness, Lieutenant-Colonel M. W. Russell, Major Thurston, Captain S. G. McAllum, and Lieutenant-Colonel G. Robinson. The toast list consisted of the following: "The King," "The Queen and the Princess of Wales and the rest of the Royal Family," and "The Guests." These were simply given from [illegible] band in each case play- [illegible] the absence of the usual [illegible] l their hosts passed the time most pleasantly and the dinner was in every way a great success.

Prize Day at St. Thomas's Hospital.—Prize Day at St. Thomas's Hospital took place on June 24th and attracted a large and fashionable gathering which assembled in the Governors' Hall of the hospital under the chairmanship of the treasurer, Mr. J. G. Wainwright, J.P., who in the course of his opening remarks said that the new nurses' home which was intended to accommodate 185 nurses was rapidly approaching completion. He also alluded to the fact that two children's wards had been added to the hospital. The out-patient department demanded increased accommodation and he hoped that that would soon be provided for by a well-matured scheme. After the prizes had been distributed by Sir Thomas Barlow he proceeded to give to the students most excellent advice. He commented particularly on the value of *vivâ-voce* examinations as a means of getting rid of the self-consciousness which sometimes is a hindrance to young medical men. He urged the importance of careful diagnosis and recommended the students to remember that the smallest details for the relief of pain were worthy of thought and study. After Sir Thomas Barlow had received and acknowledged a cordial vote of thanks the company dispersed into the various departments of the hospital and school and were entertained at a garden party held on the terrace.

National Health Society.—Dr. George Newman, medical officer of health of the metropolitan borough of Finsbury, was one of the principal speakers at the meeting of the National Health Society at the Mansion House on June 28th. In proposing a motion approving of the work of the society Dr. Newman drew attention to the increase in the number of industries which afforded employment for women. He said that there were now employed in the county of London some 720,000 women in various occupations. About 240,000 of t [illegible] at home and the remainder [illegible] places. The above create [illegible] need—for the existence of such societies as the National Health Society and he insisted on the fact that the rules of health must be taught in the homes of the people by the society. Sir James Crichton-Browne, who seconded a vote of thanks to Princess Christian for being present, observed that the public had awoke to the fact that the stamina of the people was not all that it ought to be. There was an undue proportion of sickly children and the superabundance of degeneration and infirmity afforded a large field for the labours of the National Health Society, whilst there was such lamentable ignorance among the poor in connexion with sanitary matters. It was against physiological and hygienic ignorance that the society directed its energies. Sir William S. Church [illegible] ledge of the populatic [illegible] bring home to the mothers of the people the few simple rules on which was founded all true sanitation. The meeting was held in the Egyptian Hall of the Mansion House and was principally attended by ladies.

The Gaskell Park, St. Helens, presented to the public by Surgeon-Lieutenant-Colonel Gaskell, V.D., J.P., was opened by the donor on June 23rd in the presence of the mayor and corporation.

A Medical Yachtsman.—The victory of the *Valdora* in the Heligoland yacht race is very popular among West of England yachtsmen, the owner of the *Valdora* being Dr. J. G. Douglas Kerr of Bath.

The late Dr E. Long Fox.—The first of the annual lectures which are to be delivered in memory of the late Dr. E Long Fox of Clifton will be delivered in November next by Dr. John Beddoe.

Death of a Centenarian.—Mrs. Mary Buckingham Edgcome, widow of the late Dr. James Edgcome of Brunswick-square, London, died at Surbiton, Surrey, on June 21st. She was born in Cornwall on June 12th, 1804, and for many years resided at Surbiton.

Literary Intelligence.—A third and considerably enlarged edition of Dr. Ralph W. Leftwich's "Index of Symptoms" will be published by Messrs. Smith, Elder, and Co. immediately. The last edition had a somewhat bald appearance from the multitude of unbroken columns. This has been remedied by breaking up the last chapter on Methods of Diagnosis and inserting its different parts under their respective headings. Dr. Leftwich has also added much similar matter, besides making the work more complete, and he has endeavoured in the new edition to meet the requirements of the medical student.

South African Civil Surgeons' Dinner.—The South African Civil Surgeons' dinner took place on June 28th at the Hotel Cecil, London, Mr. G. H. Makins, C B., being in the chair. There was a good attendance and amongst those present were Mr. J. Tweedy (President of the Royal College of Surgeons of England), Sir William Taylor, K.C.B., Sir William D. Wilson, K.C.M.G., Mr. W. Watson Cheyne, C.B., Mr. C. T. Dent, Surgeon-General A. H. Keogh, C.B., Mr. A. A. Bowlby, C.M.G., Dr. H. H. Tooth, C.M.G., Mr. C. Stonham, C.M.G., Mr. F. C. Wallis, Mr. G. Stoker, C.M.G., and Mr. C. G. Watson. After the usual toasts had been honoured Mr. Makins proposed the toast of "The Imperial Forces." He said that the navy let the public know very little about how or in what way changes were carried out on board ship. The "man in the street," on the other hand, heard a good deal about the army and the changes which were going on daily therein, but he (Mr. Makins) supposed that they must put their trust in Providence and hope that things would come all right. The toast was responded to by Sir William Wilson, who was principal medical officer in South Africa during the war. He said that he had always been in favour of conferring rank on the civil surgeons after a necessary period of probation. The health of "The Chairman" was proposed by Sir William Taylor and suitably acknowledged. Everyone was grateful to Mr. Watson for his successful efforts in getting up the dinner.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Registration of Nurses.

The Government has appointed the following Select Committee to consider the expediency of providing for the registration of nurses Mr. Robert Ambrose, Major Bagot, Sir Michael Foster, Mr. Arthur Henderson, Mr. Lyell, Mr. Malcolm, Viscount Morpeth, Mr. Pierpoint, Sir John Stirling-Maxwell, Mr. Tennant, and Sir John Batty Tuke.

Bills Abandoned.

[illegible] the end of the session is to be found [illegible] this week. Among the Bills dropped [illegible] r. R. Farquharson's Nurses Bill, Sir Herbert Maxwell's Sale of Whisky Bill, Sir Charles Dilke's Shops Bill, Mr. Broadhurst's Vaccination Bill, and Mr. Channing's Vaccination Prosecutions Bill.

HOUSE OF LORDS.

FRIDAY, JUNE 24TH.

Beri-beri among Chinese Coolies.

The Marquis of **RIPON** made reference to what occurred in the House of Commons on Wednesday, when Dr. C. F. Hutchinson attempted to discuss the question of the existence of beri-beri among the Chinese coolies in South Africa, and he asked whether the Government had yet received official information.—The Marquis of **LANSDOWNE** replied in the negative. He added that it seemed clear that the case was one in which extraordinary precautions of some kind would be called for and he had no doubt that they would learn in due course [illegible] ng done to cope with the outbreak. The Govern- [illegible] are that this disease was a dangerous one and it [illegible] pains should be spared to prevent its spreading. —Earl **CADOGAN**, speaking as an ex-Lord Lieutenant of Ireland, mentioned an outbreak of this disease which had occurred in a prison hospital in Dublin. Under the regulations it would not have been possible to deal with the emergency as rapidly as he wished. He, however, kept the matter in his own hands, transferring the patients to a disused prison and ordering the hospital to be cleansed. One or two fatal cases occurred but the severity of the disease was mitigated in a very short time and he thought that if this outbreak in South Africa was promptly and vigorously combated it would probably not be so severe and dangerous as seemed to be feared.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 22ND.

Beri-beri among Chinese Coolies.

Dr. **HUTCHINSON** asked the Secretary of State for the Colonies whether his attention had been called to the outbreak of beri-beri among the Chinese coolies who had recently arrived in South Africa; whether those who had developed the disease had been actually landed; whether those who had been exposed on board ship to infection had yet been sent up country to the compounds; and whether, having regard to the intensely infectious and dangerous character of this disease, from which South Africa was at present free, he would tell the House what steps had been taken to prevent the spreading of the disease in the colony.—Mr. **LYTTELTON** replied: I have received no report from Lord Milner on this subject. I have telegraphed but have received no reply. I have every confidence that, judging from the admirably efficient measures taken for dealing with the outbreak of plague, every precaution will be taken.—Dr. **HUTCHINSON** considered that this reply was extremely unsatisfactory and he asked leave to move the adjournment of the House "to call attention to a matter of urgent public importance, the imminent danger which arises from the introduction of a new highly infectious and fatal disease known as beri-beri into South Africa."—The Deputy Speaker (Mr. J. W. **LOWTHER**) held, however, that the question could not be discussed on a motion for the adjournment as it was covered, in his opinion, by one of the so-called "blocking motions" on the papers of the House.

Sore-throat in Glasgow.

Mr. **WEIR** asked the Secretary for Scotland whether he was aware that the epidemic of sore-throat which recently broke out at the Belvidere Hospital, Glasgow, was, like that at Woking last autumn and at Finchley early this year, attributable to the milk taken from cows out of health; and whether, seeing that Dr. A. K. Chalmers, the medical officer of health of Glasgow, stated that the outbreak in that city was due to teat eruption in the stock at the farm from which the milk supply was obtained, he would consider the expediency of introducing at an early date such legislation as might be necessary to insure the occasional examination by a veterinary surgeon of all cows kept for the purposes of a public dairy.—Mr. **GRAHAM MURRAY** said: I am informed by the Local Government Board for Scotland that it has Dr. Chalmers's report under consideration. As regards prospective legislation I can add nothing to the answer given to the question addressed by the honourable Member on June 13th to the President of the Local Government Board, but I may point out that under the existing law a local authority in Scotland is entitled to procure a report by a veterinary surgeon on the animals in any dairy from which the medical officer has evidence that infectious disease is likely to be spread.

Sanitary Condition of China Stations.

Sir **SEYMOUR KING** asked the Secretary of State for India whether the attention of the military authorities in India had been called to the insanitary state of the quarters and barracks of British officers and native ranks of the [illegible] a at Shan-hai-kwan, Tientsin, and [illegible] aware that at Shan-hai-kwan near [illegible] some time or other laid up with fever, dysentery, or diarrhœa, the quarters of both officers and men being in an old yamen the inclosure of which was the old bed of the river Shi-to and liable to be flooded; whether other foreign contingents at Shan-hai-kwan were well housed in forts captured by the British force in 1900 and at Tientsin had superior accommodation while those of our own troops had been reported on as in a disgraceful condition; and whether he would call for a report on the sanitary condition of the China stations and order that measures should be taken to secure healthy quarters for our troops.—Mr. **ARNOLD-FORSTER** replied: Money has been taken in Army Estimates for the improvement of the accommodation at Peking and Shan-hai-kwan but there is no information at the War Office to show the exact progress made with the work. Further, no recent information as to the health of the troops has been received at the War Office as the returns are sent to army headquarters in India but the question is one of importance as it concerns the health of officers and men and I will cause further inquiries to be made.

Tuberculosis in Ireland.

Sir **MICHAEL FOSTER** asked the Chief Secretary to the Lord Lieutenant of Ireland whether the Local Government Board for Ireland was taking the necessary steps towards remedying the insanitary conditions of the Clonmel district to which the prevalence of tuberculosis in that district had been attributed.—Mr. **WYNDHAM** replied: The Board's medical inspector directed attention in 1901 and 1902 to the insanitary condition of this district and the Board impressed upon the district council the duty of taking all such steps as were necessary to put the district in a satisfactory sanitary condition. The inspector will make another report at an early date and this report when received will be communicated to the local authority. The Board cannot compel the [illegible] action in the matter unless in pursuance of [illegible] in pursuance of the fifteenth section of the [illegible] Act, 1896. No such complaint has yet been made to the Board.

The Alleged Ill-treatment of a Child.

Sir **WALTER FOSTER** asked the President of the Local Government Board whether his attention had been called to the case of the child, named Albert Algage, who was returned to the Westminster union from the St. Giles's receiving home with marks of injury on the face and limbs; whether he had received evidence to satisfy him that the injuries were not due to punishment or to want of proper care and supervision; and, if not, whether he would order an inquiry into the treatment of the child while an inmate of the receiving home.—Mr. **LONG** said: I am aware of this case and the inspector of the district has made investigation with regard to it. As a result he reports that the bruises were not in his opinion due to punishment or to want of proper care and supervision and that in all probability they were caused by the child himself. I do not think that any further inquiry is needed.

THURSDAY, JUNE 23RD.

Small-pox in Staffordshire.

Mr. **COGHILL** asked the President of the Local Government Board whether his attention had been called to the renewed outbreak of small-pox in North Staffordshire; and whether he could state what provision had been made for hospital accommodation by the local authorities and what steps the Local Government Board proposed to take to deal with the epidemic.—Mr. **LONG** said: I am aware that an outbreak of small-pox has occurred in the Leek urban district and in connexion with it I have sent a medical inspector to visit the locality and have received a report from him on the subject. Leek is included in the district of the North Staffordshire joint small-pox hospital board and up to the date of the inspector's report at the end of last week all the cases of small-pox had been removed to the temporary hospital provided by that board. Further and better hospital accommodation seems to be required. I have already sanctioned the borrowing of money by the hospital board for this purpose. I am pressing upon the board to proceed with the works and also to consider whether even further provision may not be needed.

A Medical Officer and Workhouse Dietary.

Mr. **LOUGH** asked the President of the Local Government Board whether his attention had been drawn to the proceedings of the medical officer of the Docking (Norfolk) board of guardians who had declined to accept the decision of the board in favour of the withdrawa [illegible] se and to the fact that the medic [illegible] pints of beer a day to be given [illegible] l; and, if so, under what authority the medical officer had acted and whether the Board proposed to take any, and, if any, what, steps in the matter.—Mr. **LONG** replied: My attention has been drawn to the case referred to. One of the regulations in force in the Docking union requires that the medical officer shall prescribe proper dietaries for the sick inmates of the workhouse. It is, however, provided that no allowance of fermented or spirituous liquor given by his direction to a sick inmate shall be continued for more than eight days, unless before the expiration of that period it is renewed for a further period not exceeding eight days by his direction in writing. Subject to the regulations in force it is for the medical officer to determine the dietary of the sick inmates and I could not undertake to interfere with his discretion in the matter.

Medical Appointments in Harris.

Mr. **WEIR** asked the Secretary for Scotland whether he was aware that the Return (Parochial Medical Officers, Scotland) was inaccurate in stating that the post of medical officer of Harris was vacant only once during the seven years prior to 1903, inasmuch as the post of medical officer was vacant on two occasions for the North Harris division and also on two occasions for the South Harris division; and whether in view of the fact that the return contained other inaccuracies of a similar nature he would consider the expediency of having an amended return issued.—Mr. **GRAHAM MURRAY** replied: The Local [illegible] d has communicated with the inspector c [illegible] the information given in the return and [illegible] ows, it is not correct that the resident medical officership had been vacant since July 20th, 1896, in the northern division of the parish twice and also in the southern division of the parish twice. If the honourable Member will give the dates when the vacancies are said to have occurred the Local Government Board will make further inquiries.

MONDAY, JUNE 27TH.

A Ballinasloe Asylum Appointment.

Mr. **LONSDALE** asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that Dr. P. Kerley, who had been elected by the Ballinasloe Asylum committee to the position of second assistant medical officer, was married; and whether, seeing that the rules of the Privy Council governing such appointments provided that the second assistant medical officer must be unmarried, he proposed to take any, and if any what, action in the matter.—Mr. **WYNDHAM** said: Yes, sir. The rule prohibiting a married man from being appointed to the position of assistant medical officer of a [illegible] universal application throughout the United [illegible] in an Order of the Lord Lieutenant in Cou [illegible] I am advised that it would be most undesir [illegible] public service to depart from the rule and th [illegible] no power to dispense with its observance.

Fees of Public Vaccinators.

Mr. **RUNCIMAN** asked the President of the Local Government Board whether he had received any protests against the amount of minimum fees payable to public vaccinators under the Vaccination Order of the Local Government Board of 1898; whether he was aware that in the Gateshead union there were, during the four years previous to the passing of the Act, 6378 primary and 230 revaccinations by public vaccinators, in respect to which fees were paid amounting to £753 12*s.* 6*d.*

and during the four years since the passing of the Act there had been [illegible]

TUESDAY, JUNE 28TH.

Beri-beri.

Several questions were put to the Secretary of State for the Colonies in regard to the outbreak of beri-beri among the Chinese coolies in [illegible] replied that although he had [illegible] official information no reply [illegible] it would be found that there [illegible]

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

DEATH.

MURPHY.—On June 28th, at 6, Thornhill-crescent, Sunderland, the residence of her son, Sarah Murphy, widow of William Chapman Murphy, M.D., aged 90.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MR. BLANK OF PICCADILLY CIRCUS.

On Feb. 20th of the present year we drew attention in The Lancet to an advertisement in the *Barbados Advocate* of one "G. Thomson Blank (late of Piccadilly-circus, London)" who was described as "Dental Surgeon to His Excellenc [illegible] Governor of Barbados, Lady Hodgs [illegible] advertisement now appears in the [illegible] know whether the Governor of Barbados has given his authority for this use of his name—especially in view of the fact that the advertiser says he is in Barbados principally on a health visit—and, if not, why some steps have not been taken to prevent G. Thomson Blank from making an improper use of the name of one of the King's representatives.

THORNE DEFENCE FUND.

To the Editors of The Lancet.

Sirs,—We beg to enclose a further list of subscriptions in aid of the above fund. The full amount required having been received the above fund is now closed.

We are, Sirs, yours faithfully,

Walter S. A. Griffith, M.D. Cantab.
Walter Tate, M.D. Lond.
June 29th, 1904. Douglas Drew, F.R.C.S. Eng.

"MARTIN'S UP-TO-DATE BEGINNER'S TABLE-BOOK. FOR SCHOOLS AND HOME TEACHING."

In *the review of this book published in* The Lancet *of April 30th, 1904,* we stated that "we hardly think that the pupil should be told that 'all weights and measures not appearing in the following tables are purposely omitted to prevent a pupil's mind from being crammed with a lot of nonsense.'" Mr. A. J. Martin, the compiler of the table-book, calls our attention to the fact that the words appearing in his table-book are: "All weights and measures not appearing in the following tables are not authorised by Parliament and are therefore 'purposely omitted' to prevent a pupil's mind from being crammed with a lot of nonsense." Mr. Martin thinks that the omission of the words "not authorised by Parliament and are therefore" is very misleading to our readers. Although the words were omitted by a *lapsus calami*, which we regret, it does not follow that things which are not authorised by Parliament must be nonsense.

CHILD-STUDY.

To the Editors of The Lancet.

Sirs,—Will any of your correspondents be so kind as to tell me where I can obtain some details of the physical and mental development of children from birth up to the age of 14 years? I want to know, for instance, the normal height, weight, and head measurements at various stages and, in fact, any details which will be the means of making child-study really useful. The ordinary text-books on physiology and psychology do not give this information and it is exceedingly difficult for students to carry out observations upon the children they are studying without some accurate guide. I may add that the observations made in this way should help teachers to determine, among other things, whether a child is fit for physical exercise and whether his bodily state is such as to call for medical aid. Thanking you in advance, I am, Sirs, yours faithfully,

June 26th, 1904. "Child-Study."

THE SELF-FILLING PEN.

A form of pen, "fountain," "stylographic," &c., which can be carried about ready for use is almost as indispensable now to a medical man as it is to a journalist; and it is not surprising, considering the demand for the pens, that various manufacturers have been able to make greatly improved patterns. We have recently had brought to our notice a "self-filling" pen in which, by a simple arrangement of a lock ring, a bulb, and a presser bar, the pen can be filled without any of the usual trouble of unscrewing and without the intervention of any sort of filler. The pen is simply held point downwards in clear ink, a small bar is pressed, and into the vacuum so created the ink rises. The saving of time and trouble is very great and as the pen is easily cleaned as well as easily filled, and is thoroughly well made, it would seem to be sure of a successful future. It is manufactured at low prices by the Conklin Pen Company and sold by the American Agencies, Limited, 38, Shoe-lane, London, E.C.

THE NATIONAL FIRE BRIGADE UNION.

The National Fire Brigade Union, representing 600 towns and possessing a membership of over 12,000 firemen, has decided to hold its annual camp and competitions at the Crystal Palace from Monday, July 18th, to the following Saturday. The men will be housed in tents pitched in the most beautiful part of the grounds, extending from the Cedars Grove to the Centre Walk, and although, of course, the exigencies of their calling will prevent all the men being off duty for four days together, there never will be less than 3000 men under canvas. Only the smartest brigades, those which have successfully passed through the preliminary trials, will take part in the displays and competitions which are to be held on the broad Firework Terraces. The grand review is fixed for Thursday, July 21st, when the medals and shields will be distributed by the Duchess of Marlborough.

THE INHABITED HOUSE DUTY REPEAL ASSOCIATION.

A correspondent *informs us that he has parted with 2s. 6d.* as a subscription to this society in response to an application made to him by a man giving the name of W. B. Benham and the address of Albert-buildings, Queen Victoria-street, London. He wishes to know what the position of this association is. We have not ourselves any information on the subject. Possibly some of our readers may enlighten us. We observe that at the address given an association of the name exists.

◆

Hector.—The advice to be given to the unfortunate residents in a *cottage where a corpse has to remain among them is not easy to* suggest. The room should, of course, be freely ventilated, screened from sunlight and flies as in the case of mortuaries and shut off from the cottage, but where this is impossible it is not of much use to give the advice. The body ought to be removed to a mortuary, but if there is not a mortuary the distressing circumstances mentioned by our correspondent may ensue.

D.P.H.—We are not in a position to give our correspondent information. The examination has not yet taken place, the regulations being published for the first time in this week's issue of The Lancet. There will be no harm in our correspondent applying to the university lecturer in medical jurisprudence, who happens to be the gentleman most likely to be able to give the information.

An Observant Pharmacist writes a very sensible letter but in spite of his pseudonym he has failed to observe a very prominent factor in the present position. There are districts where medical men must dispense their medicines because there is no one else to do it, the locality not affording a livelihood for a dispensing chemist or druggist.

Hope does not understand the situation and attributes to something which she calls medical etiquette proceedings that are adopted for the safety of the public. The second case appears to show that a condition which was at first unrecognisable became obvious after rest in bed, when operation gave relief.

Ignarus will feel much obliged if anyone can suggest a permanent residence in the Midlands, town preferred, but not essential, suitable *for a family suffering from rheumatism and gout. Any suggestions* will be highly valued. A place not too cold and sheltered from keen winds is advisable.

An Old Hospital Resident.—We regret to be unable to publish the really humorous story but we think that if it were seen by the public it would convey a very wrong impression with regard to the obstetric assistants nowadays sent out from the general hospitals.

Mr. S. Thistlethwaite sends us a complaint with regard to an advertisement which did not appear in our columns. The questions that he asks us should clearly be directed to the editor of the work in which the advertisement appeared.

Student.—Observations have been made upon the lines indicated, we believe.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not, in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1904, which was completed with the issue of June 25th, and the Title-page to the Volume, are given in this number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1904 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

During the week marked copies of the following newspapers have been received:—*Westmeath Independent, Southampton Times, Aberdeen Free Press, Aberdeen Free Press (Weekly), Westminster Gazette, Windsor and Eton Express, South Wales Daily News, Walsall Advertiser, Surrey Advertiser, Reading Mercury, Mining Journal, Local Government Chronicle, Yorkshire Herald, Daily Chronicle, Standard, Liverpool Post, Eastern Morning News, Hertfordshire Mercury, Evening News, Macclesfield Courier, &c.*

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return o testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

A Clinical Lecture

ON

CASES OF APPENDICITIS

Delivered at St Bartholomew's Hospital on Feb 17th 1904,

BY ANTHONY A BOWLBY, C M G,
F R C S ENG

SURGEON TO AND LECTURER ON SURGERY AT THE HOSPITAL

GENTLEMEN —My own experience of clinical lectures is that the more truly they are clinical and the more intimately they deal with cases in the wards or with cases which have recently been in and the less like books they are the better In looking over the cases which have been in my own surgical wards during the last few months I have been struck by the number of cases of abdominal surgery there have been and amongst these there has been quite a large proportion of cases of appendicitis But in addition there have been cases of gastro intestinal trouble and also surgical cases in connexion with the ovaries and uterus I shall have an opportunity of saying something about these another time What I want to speak to you about to day is some of the lessons which may be learnt from the cases of appendicitis which we have had in the wards in the last three or four months I find we have had 17 cases of appendicitis which have come to operation and 13 of those 17 cases have been non suppurative, the remaining four having been suppurative When we come to classify these and to see how it was that these patients came to have operations done upon them we find very varying histories Let us take one characteristic sort of history that of a girl in Stanley ward who was one of the most recent to be operated upon She is 16 years of age and gives this story She has had four attacks of abdominal pain The first attack occurred in June 1902—that is to say nearly two years ago—and came on suddenly in the night It was localised on the right side low down was accompanied by sickness and for several days afterwards by constipation and, her medical attendant adds by fever So you see it was a fairly typical case of appendicitis The pain at night is a very curious fact in these cases of appendicitis In a large number of patients the pain comes on at night and I have no explanation of that to offer you But you have to consider what it is that could cause a sudden attack of pain in the night when the person is not doing anything actively by which he can hurt himself and at a time when the last meal that has been taken has already been in the stomach or intestines for many hours At any rate this otherwise apparently causeless attack of pain coming on at night is very suggestive of appendicitis Well, this girl felt herself unable to go about her work in the morning but did not take to her bed until the evening She remained in bed two days and then got up and felt quite well It was a very transient attack She has had four such attacks up to the present time all of them more or less of the same character as those which I have been describing It is alleged that her last attack a month ago was more severe and that she remained in bed for eight days She goes on to say that if she takes any active exertion it brings on an attack She tells us also that she is unable to eat anything hard and difficult to digest without bringing on an attack and that a long walk or bicycling has a similar effect Now that is a pretty typical instance of one class of case and the following questions are suggested What is it that happens to cause the sudden pain? How is it that it also goes away so suddenly? And also how is it that the pain leaves the patient so little the worse for it?

There is another class of case altogether illustrated by children as well as adults who have been in the wards and their histories have been of attacks of abdominal pains which have not been localised anywhere in particular and were of doubtful nature Let me tell you of a boy whom I have recently operated upon elsewhere as he is a characteristic case of the kind I am now alluding to for in his case the attacks of pain were not as in the girl localised to the right iliac fossa He was alleged to have been liable to attacks of so-called 'acute indigestion for the last two years The story was that often at night and sometimes in the early morning soon after getting up he would have attacks of sickness and pain and it was not thought much of because it was believed that he must have eaten something which disagreed with him As I have said, he had no localised pain but he had attacks of sickness which, however, did not alarm his parents at all for they concluded that they were 'stomach attacks and the boy got over them in the course of about a day on the next day being as well as ever Then a few weeks ago he had measles At the time he had measles he had one of these attacks and the parents said to the medical man who was looking after him that they were quite used to them The medical man inquired further and found that they were frequent and very transient but he could not find anything in the boy's abdomen to account for them The boy got over the measles and at the end of his illness when he was up and about again, he had another attack which began like the others but was more violent and then he complained of pain in the right iliac fossa He had never previously in other attacks complained of pain there but said that the pain was all over the abdomen—a colicky sort of pain This time he was found by his medical attendant to have a definite pain in the right iliac fossa and also some tenderness there, so that he could not bear it to let [illegible] hed And of course, the medical man said at once This is an attack of appendicitis The temperature was found to be 102 6° F and the patient was altogether very ill when I was asked to see him I did not see him that night but I did next morning He had had a good night had completely lost his pain had no tenderness and appeared to be perfectly well So there again the attack was exceedingly transient even more so than the attacks in the case of the girl But in this boy there was a history of a great many attacks of pain in the abdomen, though none of them had given rise to the slightest suspicion of anything being the matter with the appendix Now I want you to remember first of all that a very large number of attacks of slight appendicitis in young people children particularly may be associated with no pain in the iliac fossa at all and there may be even no tenderness, but in most cases that is not even examined for because as in the case of this boy the parents do not call in a medical man These are the sort of attacks in which the patient is almost certain to have frequent relapses The case of the boy I have referred to illustrates pretty well that of another boy who is now in Darker ward There is a history in this case of many attacks in which there was no evidence that the appendix was affected and yet at the end of them all there came an attack which was definite appendicitis But you can see now that although he has probably had only this one typical attack of appendicitis proper he has had many attacks of abdominal pain and sickness which were really due to the same cause

The next point I want you to consider with me is what was the matter with these appendices when I took them out? In the case of the girl who had had four attacks what was there to show? When I opened the abdomen there were no adhesions and when I got the appendix outside the cavity of the abdomen it presented practically nothing abnormal except that it was a little swollen and that it was sharply bent and kinked so that it was bent almost to a right angle by a very short mesentery Then as to the appendix of the boy whom I have been referring to who had but one definite attack of acute pain and distension and high temperature, though he had had many other attacks which had not been diagnosed as appendicitis what was the condition of his appendix? It was very long it contained some fæcal matter and at its tip it was distended But there were no adhesions no inflammation and in the neighbouring peritoneum there was nothing to make you say that the peritoneal surface had ever been inflamed at all I have no doubt that the proper explanation of these attacks which were so transient that they passed away in the course of a few hours leaving the patient apparently perfectly well and no worse for the bout was that the main lesion was not an inflammatory one I am sure that in these patients there

f the whole thickness

ical coat for if that

lhesions in the neighbourhood after so many attacks Yet in these cases we are referring to there were no adhesions Well what is the explanation of the attacks of pain? What is it that causes the sickness and the griping and how is it that these so suddenly pass away? I am sure myself the explanation is that there is a distension of the appendix by secretion and that when this gets out after having been blocked up the whole of the symptoms rapidly subside. There have never been anything more than a distension and retention of such mucous fluid as may be formed in the appendix itself. The next thing is, what is it that blocks up the appendix, and why cannot the secretion get out? The answer to that, first of all, is to be found in the condition of both of these appendices which each contained fæcal matter; and if that fæcal matter is allowed to remain there a sufficient time it becomes hard and forms a concretion, although for long before that it has obstructed the passage through the tube. The appendix ought to contain no feculent material at all. Next, I told you that the mesentery was very short in the case of the girl and that the appendix was consequently bent. That bending or doubling up of the appendix you may easily conceive makes it difficult for the contents to pass along and so may cause distension. Then in many other cases when you remove the appendix you will find, on laying it open, that at some point it is very much narrowed. If you were speaking of the urethra you would probably apply to it the term "stricture" and I think you may use the same term quite correctly in connexion with the appendix. Any one of these conditions, then—namely, fæcal contents, kinking, or stricture, or more than one of them, will be found to be quite sufficient to account for the stopping of the lumen of the appendix and the retention of secretion inside it. It is in those circumstances I believe that these sudden, acute, transient attacks occur. Next, why do they occur? What brings them on? Why should a patient have an accumulation of anything at all inside the lumen of the appendix? Let us remember this: that the lumen of the appendix is after all very much like the lumen of the rest of the intestinal tract, and that, just like the rest of the intestinal tract, it may be affected by external conditions, such as cold and wet, and also by internal conditions such as bad food, or food which irritates the inside of the bowel. So that any of these conditions which we know may easily cause catarrh in the intestine may, and probably do, cause catarrh in the appendix. Whatever is the pathology of catarrh in the intestine is also the pathology of catarrh in the appendix and I think it is a very easy thing to explain how, in a part where catarrh has occurred before, thick mucus may be rapidly formed as a result of either errors in diet or exposure to cold and wet.

Now let us consider another class of case altogether. There was a soldier sent in with the story that he had had a very acute attack of appendicitis and that the army authorities were unwilling that he should return to serve until he had had his appendix removed. We found that he was a fine, healthy-looking young man, and the history which I got from the surgeon was that he had had a very violent attack of acute appendicitis with some peritonitis, that he had been taken ill with a great deal of general abdominal pain, sickness, and much flatulent distension of the bowels, a high temperature and rapid pulse. The question was raised whether he ought to be operated upon there and then by the surgeon, but they managed to tide him over the attack, though it was very severe and prolonged, and it was a week or two before his temperature came down to normal. Altogether he was in bed for several weeks and then he gradually picked up and got well enough to come to the hospital to have the appendix removed. I operated upon him and when I opened the abdomen I found that everything was adherent in the right iliac fossa. After a good deal of trouble we freed the omentum and separated the adherent intestine and after further trouble came down to the under part of the cæcum where the appendix is attached. There we found a mass of old granulation tissue and we found also the stump of the appendix and that was all. The appendix had been destroyed and undoubtedly the rough bare place which we exposed on the under surface of the cæcum was the place where there had been an abscess which had probably opened into the bowel. As it turned out, the operation upon that man, surgically speaking, was unnecessary. Of course it was necessary from one point of view because unless something could be ascertained definitely as to the condition of the appendix and the man's liability to have another attack of appendicitis it was evident that he was not fit to be a soldier. In precisely similar circumstances I operated a year ago upon a young officer. His story, which again was sent to me by his army medical officer, was a clear one. It was as follows. When near the north-west frontier of India he was taken with a very violent attack of pain and sickness which was believed to be due to peritonitis. He was desperately ill and he lay in bed for six weeks. His recovery was very tardy. He was then told: "If you are to stay in the army you must get rid of your appendix." And he came over here for the purpose of having it removed. I operated upon him and found almost an exactly similar condition of things to that I have just described. The man had quite evidently had acute inflammation with the formation of an abscess and complete destruction of his appendix. And though we found the stump of the appendix—and I should not have been satisfied if I had not—we became convinced that nearly the whole of the appendix had been destroyed. We felt certain that he had had inflammation which had gone on to suppuration, that this suppuration had destroyed the appendix, and that pus had made its way out by an opening into the cæcum. There again there was really no necessity to have operated. You must remember then that the acuteness of the attack is not by any means an indication of the necessity for the subsequent removal of the appendix if the patient is an adult but rather the contrary. Indeed, if you find that an adult has had a very violent and prolonged attack of such severity as to threaten his life, the probability is that there may be no necessity to operate for the removal of his appendix, because it is very likely that it will have been destroyed. In some such cases as these you will find a definite history that pus has been passed by the bowel, and if you can definitely ascertain that pus has been passed by the bowel I think you may say that there will most likely be no necessity for operation. But you cannot always get that history, because the pus may be disintegrated in the bowel or may find its way only slowly into the intestine so that no great quantity at any time may find its way into the motions, and then you have to rely largely upon the history of the severity of the attack. For many years I have been inclined to advise people not to have the appendix removed because of one very severe attack, and the more severe, the more prolonged, and the more dangerous that attack has been the more it has seemed to me that there is no necessity for operation, for the severity of the attack has probably resulted from an inflammation which has exterminated the very organ which was the seat of the mischief. A fortnight ago I operated upon a patient in whom there was a history of two attacks, and it was because there had been two attacks that I advised operation. The first attack was not a bad one, but the second was. Still it did not seem to be so bad as to make it probable that the appendix had been destroyed, so I operated. When I opened the abdomen I found everything matted to the side of the abdominal wall. With a good deal of difficulty and trouble I separated the adherent cæcum which was unusually high up, and having got it out into the wound and looked for the appendix we found the place from which the appendix sprang from the cæcum and after tracing it through some inflammatory exudation and adhesions we found it came to an abrupt termination and was adherent to the cæcum [illegible] During that examination which wa[illegible] satisfy myself that the appendix wa[illegible]nd that I had separated adhesions [illegible] a hole into the cæcum. I had not made the hole, but I had uncovered a hole which had previously been covered by the adhesions which had closed it. That was another case in which suppuration had evidently destroyed the appendix and in which except for freeing adherent omentum my operation had done no particular good; indeed, if one had made much of an opening in the cæcum it might have done harm; but I managed to close the hole and to shut up the wound. Probably the appendix in this case had been destroyed by the second attack. I could multiply these cases and of those which I have seen where there has been a definite discharge of matter by the bowel I have never had one of them afterwards in which it has been necessary to remove the appendix, nor yet where I have heard that the patient has had another attack. Therefore I want you to appreciate that there is a great deal of difference between these cases of a single, acute, prolonged atta[illegible]haracter, especially in adults, and those [illegible] attacks in children and young people [illegible]ransient character which are liable to go on recurring and to get worse. It is for such attacks as these that I always advise the friends and the patient to have an operation [illegible] the appendix by fluid, which [illegible] into [illegible] and t. [illegible] patier [illegible]

Then there are some oth [illegible] which I will allude briefly, cases [illegible] of the patients are in the hospi [illegible] nth in Darker Ward who came [illegible] home to-day, but when he wa [illegible] e was very dangerously ill. His age was 18 years and the history was that five days previously on a Friday evening at nine o'clock he felt pain in his right groin and was sick all night. In spite of that he got up to [illegible] when he [illegible] e on to [illegible]

[illegible] erature [illegible] from 96 [illegible] That is, of course, the wrong way round; instead of his pulse coming down with his temperature it rose. I did not operate upon him that day; I thought that as he had only just been put to bed we would wait and see what was [illegible]

[illegible] it had risen to 120 and he [illegible] pain. His temperature w [illegible] opened his abdomen on the right side and found that he had a very extensive abscess which went down to his pelvis with very ill-defined boundaries. I expect that if I had opened his peritoneal cavity in the middle line or on the other side I should have found that there was *some inflammation of it*, though probably no pus inside the general peritoneal cavity. The reason we operated upon him was partly because of his increasingly rapid pulse and partly because he continued to be sick in spite of our stopping [illegible] uth. His [illegible] us. When [illegible] of stink- [illegible] tissue all round, and for a long time afterwards the patient was desperately ill though he ultimately made a good recovery.

Now let me tell you of another case which I have seen very recently which illustrates this point about the temperature very well. A girl, aged ten years, was taken ill suddenly, with a rigor and pain in the abdomen. The history was that [illegible] months previously when in the [illegible] similar attack *accompanied* by [illegible] for three days and difficulty in [illegible] he abdomen, and difficulty in [illegible] this there was a temperature of [illegible] t over the worst of that attack [illegible] some abdominal discomfort persisted for several weeks. The next attack began on a Thursday and on the Friday I saw the patient. The abdomen was distended and the child was very sick, the pulse was 140, and the temperature when she was put to bed was 102°, though that morning it had come down to just under 100°. *The same evening, no food having* been given by the mouth, she had been less sick. I did not see her on the Saturday as she was better and the sickness had stopped, but on the Sunday her temperature was normal and her respirations were normal too. The pulse was 130. Sickness had not returned, the abdomen was not distended, the bowels acted with enemata, but there was a great deal of pain in passing urine. The absence of sickness was a good [illegible] nen was also [illegible] moved very [illegible] was Sunday [illegible] he pulse did [illegible] next morning with a normal temperature, [illegible] he night the child had been very sick again [illegible] in and the [illegible] l, t [illegible] in [illegible] s [illegible] been discont [illegible] better to op [illegible] temperature, [illegible] more *important to lay stress on the return of sickness and* the hard and fixed abdominal wall. I therefore operated and found pretty much what I expected to find—namely, a considerable collection of pus in the pelvis, the evacuation of which gave speedy relief

Let us take another case. There is a boy at the present time whom some of you have seen in No. 2 Darker Ward; he came in with general abdominal distension but very litt [illegible] 0. When I saw [illegible] of the abdomen [illegible] or pain; there [illegible] operating upon [illegible] day he continued [illegible] ole satisfactory and Mr. R. C. Bailey, who [illegible] led that there was still no indication for an [illegible] ally as the bowels had been freely opened [illegible] *more easy. But instead of the symptoms* further subsiding the patient was taken rather suddenly very much worse the next day and Mr. Bailey found him in an almost pulseless condition and desperately ill, so ill that the anæsthetist hardly thought he would get him off the table alive. [illegible] had [illegible] had a large collection of pus and general peritonitis. [illegible] tunately up to the present time he seems to have gone on sufficiently well to lead us to hope that he will recover altogether; but he has had many complications and one of them is very common in cases of diffuse appendicitis—namely, suppuration in the upper part of the *abdomen as well as in the lower part—a subdiaphragmatic* abscess. And he has had another complication which is common—namely, a secondary abscess in his pelvis, that is to say, he has had diffuse peritonitis with localised collections of pus in the upper and lower parts of his abdomen and pelvis. A curious thing about his case is that in each fresh abscess the symptoms have been cumulative. He went on well for a week after the abdomen was freely opened and at the end of that time he was again taken very much worse and Mr. Bailey accordingly operated and let out pus from beneath the diaphragm. Then again he went on satisfactorily for a week and whenever I saw him he appeared to be doing well and expressed himself as cheerful and happy and free from pain. But I received a message one evening to say that he had been suddenly taken much worse. I found he had a good deal of tenderness over his pubes and difficulty with his urine, and I opened up his abdomen by an incision in the middle line and let out a large collection of pus in his pelvis, about one and a half pints, which probably had been there for several days, yet had given no symptoms of its presence. It seemed that until the accumulation went beyond a certain point there was no evidence forthcoming of what was going on inside.

Now, another word about one condition noticed in two of the patients whose cases I have mentioned—namely, painful micturition. You [illegible] that there is pai [illegible] *deal of difficulty* [illegible] of that is almost always to be found in the fact that in these cases the inflammation has spread into the pelvis. In many cases where the pain is yet worse there is a definite collection of pus in that region, a pelvic abscess. In the little girl of whom I spoke the pain was most characteristic and it was the pain on passing urine which made one say that very likely there was a collection of pus in the pelvis, for when there is pelvic peritonitis micturition is often very painful indeed, though there is little to be felt externally. When you remember that pus forming in the pelvis may not be perceived by examination of the anterior abdominal wall you will see how important it is to pay attention to the complaint of painful micturition and to the examination of the patient per rectum. In the majority of cases of appendicitis such an examination is of as much importance as examination of the anterior abdominal wall. For you must remember that a large part of the peritoneal area is not accessible through the anterior abdominal wall by palpation and you can often find per rectum a definite swelling which would not be evident from the front. You will thus be led to diagnose pelvic peritonitis which otherwise might have escaped you, for the rest of the peritoneum of the patient may be completely free from mischief.

The Milroy Lectures

ON

DEATHS IN CHILDBED: A PREVENTABLE MORTALITY.

Delivered before the Royal College of Physicians of London on Feb. 25th and March 1st and 3rd, 1904,

BY W. WILLIAMS, M.A., M.D., D.P.H. OXON.,
MEDICAL OFFICER OF HEALTH TO THE GLAMORGAN COUNTY COUNCIL.

LECTURE III.[1]

Delivered on March 3rd.

PREVENTIVE MEASURES.

MR. PRESIDENT AND GENTLEMEN,—Notwithstanding the precautionary measures adopted in general midwifery practice, the alarming fact that 4000 mothers are annually lost in England and Wales still stares us in the face. What, then, is our duty in respect of this high puerperal mortality? Are we to trust to the repetition of *Abracadabra* as extolled by Sammonicus, or are we to go to bed and dream about it as directed by Galen? This we have tried long enough and naturally without any beneficial result. This same question was asked many years ago and it occurred to some benevolent persons that the solution of the problem was in the establishment of lying-in hospitals, where women—poor, destitute of comfort and means, as many are at their own homes—should be received and delivered. These institutions after many years of anxious trial have answered admirably and it is to means similar to those which have been found efficacious in diminishing the mortality in them that recourse must be had to procure a similar reduction in general practice. To use the significant and beautiful sentence penned by the late Mr. T. W. Thompson of the Local Government Board, "Such improvement can only be brought about by a *full* appreciation of *all* that is known of the etiology of the disease and an adequate sense of the responsibility on the part of *all those* brought into relation with the lying-in chamber." Dr. Cullingworth has strongly advocated the more general use of antiseptics in private practice and has particularly urged that every practitioner should recognise his individual responsibility in this matter. To bring about this diminution of mortality is a work in which various sections of the community must take part, such as the parturient women themselves, the midwife and medical attendant *in particular*, the medical officer of health, the sanitary inspector and public bodies such as local sanitary authorities and county councils, and the legislature.

Young women about to become mothers require instruction and special care, for by leading a natural life in conformity with the laws of health they often save both themselves and offspring, for few women in advanced pregnancy can stand the hard work to which, alas, they are too often exposed. Although childbirth is a physiological process and in favourable circumstances (where the mother has been previously taken care of) is attended with little danger, yet every childbearing woman looks for some help in her travail; but many, even in these enlightened days, are left to nature or to ignorant midwives.

Women in all ages and countries have done much noble work as midwives and as nurses—the mother of Socrates was a midwife, "brave and burly." A large proportion of mothers have been from time immemorial attended by midwives, and educated midwives as well as medical men are required to secure the best chance of life to the mother and to the child. This is a natural and excellent arrangement, as midwifery is a business for which intelligent women are admirably fitted. Until lately, and even now in some places, it was assumed that midwives were born and not made and their training was entirely left to chance. At the present time it rests on very unsatisfactory foundation, although systematic instruction has been imparted to them in some quarters. A very common cause of death in childbed is simply "the want of skilled assistance" and a mother's life often hangs on a simple act which can be easily performed by any intelligent woman who knows her work. In the absence of this the mother dies. There is scarcely a person whose life, or whose mother's life, might not at one time have depended upon the skill of a midwife. Newton had a narrow escape; and Goethe begins his autobiography by saying that through the unskilfulness of a midwife he was born for dead and that only after manifold efforts on the part of those around him he saw the light of day. It is true that a medical man can be called in, but in scattered and mountainous districts he is not always at hand when danger is imminent. To discover danger a knowledge of its sources is required and those of us who have come in contact with midwives of the Sarah Gamp type are well aware that ignorance does not diminish their self-confidence. No one who has reflected upon this subject, and certainly no one who has had practical acquaintance with it, will contend that the annual loss in England and Wales of over 4000 mothers in childbed is not deplorable. Certainly nothing should prevent those that have the public health at heart from giving this subject their most attentive consideration. This matter has not received the attention it deserved either at the hands of the legislature or at those of public authorities. The provisions of the Midwives Act, 1902, will, in my opinion, meet the case to a great extent, but I would suggest that the training of midwives is a typical form of technical education and is a work that ought to be undertaken by county councils. Certainly, in some way or other, assistance should be forthcoming to help intelligent women to fit them to render "first aid" to their sisters in travail. The utility of a recognised body of educated midwives acquainted with the plain doctrines of health and capable of rendering assistance during labour would be incalculable to the community at large. I do not mean that midwives should displace medical men in any way, where such can be obtained, but they should be in a position to render valuable aid before the arrival of the practitioner and to carry out his instructions faithfully as to the administration of remedies, the use of the syringe and catheter, general cleanliness, the warming and ventilation of the room, the diet, and a thousand and one other acts on which the health and life of the mother depend. The medical officer of health and the sanitary inspector can also render great help towards diminishing this mortality. The infected premises should be visited as soon as possible and as soon as the case is over all sanitary defects should be remedied, the house should be fumigated, and the clothing of the midwife, the soiled linen, and the like of the patient should be passed through a disinfector or, failing this, be destroyed. The midwife should undergo thorough antiseptic ablution, especially of such parts as the finger nails, that are the most likely to retain infection. This is impossible in districts where disinfectors have not been provided, and they are many. It therefore becomes incumbent upon local authorities to procure such, and none should be considered fully equipped unless it has a bath-room and dressing-room in connexion with it. Before the medical officer of health can be expected to accomplish these duties the tenure of his office must be secure and his salary must be adequate.

There are other avenues—now more or less shaded or obscured by the midwives question—along which some of our efforts might well be directed. Every girl among the poor and artisan classes should be taught the elementary principles of nursing and hygiene. The establishment of lying-in institutions should be encouraged in these localities and the parturient poor induced to become patients over their confinements. It is true that the guardians of the poor provide a lying-in ward in their workhouse infirmaries; and there are scores of women in poor circumstances who would gladly enter a maternity but refuse the lying-in ward of the workhouse because of the *stigma pauperis* connected with it and accept the alternative of remaining at home, to be there—may be, in the heart of unhealthy influences—attended by unskilled women and often to face the risk of being fatally infected. The dissemination of elementary knowledge of the nature indicated might well be encouraged by our county councils and local authorities and this matter is engaging the attention of the Glamorgan county council with a view to secure the better training of midwives. I have endeavoured to show that a very large number of poor women who are unable to obtain the services of medical men are attended in childbirth by midwives alone; how often it is that fatal results, and even epidemics, follow ignorance on their part of the means to prevent infection, and their inability to diagnose danger in time, and I feel convinced that this mortality in childbed among the poorer classes can be very materially diminished in the several ways I have indicated, especially if they are attended by sober and intelligent women, acquainted with the plain doctrines of health, and possessing an elementary knowledge of midwifery.

---

[1] Lecture I. was published in THE LANCET of June 18th (p. 1701) and 25th (p. 1772) and Lecture II. in THE LANCET of July 2nd (p. 4), 1904.

Before dealing with the Midwives Act it would be well to give a very brief epitome of the various steps taken that [illegible] I am indebted to contributions and notes [illegible] phreys, honorary secretary to the [illegible], the particulars contained in the following historical sketch. He who would wish to write anything like a complete history of these steps would have to ransack the history of England and to search the records of Church and State for centuries in order to obtain the ups and downs of the Guild of Midwives. I do not propose, however, to refer to the past except so far as it is necessary to explain the condition of affairs that has caused the postponement in England of legislation which was secured by nearly every other European nation many years ago. Before the time of Henry VIII. the medical profession was controlled by the Church and the bishops licensed physicians, surgeons, apothecaries, and midwives alike, but when the faculty began to manage these matters midwives were ignored. At this time there was no clear difference between the branches of medicine, surgery, and midwifery, and it was after the formation of the Royal College of Physicians of London in 1518 that the change was brought about. In 1541 an Act uniting barbers and surgeons was passed. In 1618 Dr. Peter Chamberlen entreated James I. "that some order may be settled by the State for the instruction and civil government of midwives," and it was his son, who was physician to three kings and queens of England, that moved the Court to organise midwives into a company. This was effected by the Royal College of Physicians and Dr. Chamberlen alluding to the arguments of his opponents says: "The objection infers this much—because there was never any order for instructing and governing midwives therefore there must never be. Because multitudes have perished therefore they must perish. Because our forefathers have provided no remedies, nor knew any, therefore we must provide none, though we know it. If all our forefathers had subscribed to this argument there had never been beginning to those conveniences we now enjoy, and we had been left to the world's first ignorance and nakednesse." From that day to this proposals have continued to be made from time to time for the instruction and government of midwives, and during the seventeenth century Harvey began his work of raising midwifery into the comparative light which he created.

It was after the invention of the obstetric forceps in the seventeenth century that men midwives began to take up the work in earnest and by the middle of the eighteenth century their number and notoriety had so increased that the competition between them and midwives actively commenced, and gradually midwives fell into disrepute, and men midwives gained a stronger position in the mind of the profession and the public. The death of Princess Charlotte of Wales and her unborn son, a death which led to the ascent of the late Queen Victoria to the throne, did much to accentuate this progress and for the first time in our history a Queen of England was attended in her confinement by a man. The control of the Church over midwives seems to have died out by this and from that time there has been no legal control over them up to the passing of the Midwives Act. The dawn of scientific midwifery was accompanied by efforts of a more or less spasmodic and half-hearted nature to raise the status of midwives and when lying-in hospitals were first established these efforts became more and more continuous and firm and many proposals were from time to time made, stimulated doubtless by the fact that nearly every country in Europe had by this time framed enactments dealing with the instruction and supervision of midwives. In 1813 the Society of Apothecaries appealed to Parliament to legislate on this question but it failed. Unhappily Parliament was so prejudiced against midwives then and long afterwards that "the committee of the House of Commons would not allow any mention of female midwives." Professional feeling also against man midwifery had assumed a strong character and the Royal College of Physicians of London passed a by-law prohibiting any person practising midwifery admission to its Fellowship. "The Obstetrical Society"—the ancestor of the present one—was then started and the object which it adopted as its basis was "the amelioration of the political position of the male and female midwives" and petitions by it were addressed to the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries, asking them to cooperate to restrict the indiscriminate practice of midwifery, with the result that the Society of Apothecaries alone was found to be willing to undertake an examination in midwifery but had no legal power to do so. Notwithstanding this it at once presented a memorial to the Home Secretary, praying that it and the Royal College of Surgeons of England (which had already fallen in line with them) should be given the necessary power to institute examinations in midwifery and making it penal for any *man* to practise midwifery unless he was a legally qualified physician, surgeon, or apothecary. Eventually the society succeeded in establishing an examination in midwifery and in the admission of obstetric practitioners to the Fellowship of the Royal College of Physicians of London and to the Council of the Royal College of Surgeons of England. After these its first successful attempts on behalf of the male members of the obstetric profession, the society qu[illegible] contemplated.

In 1843 [illegible] a clause in [illegible] midwifery [illegible] College of Physicians of London established the diploma of Licentiate and made midwifery a compulsory subject, and it was also about this time that the present Obstetrical Society held its inaugural meeting when numerous references were made to the uneducated and uncontrolled condition of women who were allowed to practise midwifery and to the unhappy lot of their patients, and to the excessive mortality in childbirth that was taking place throughout the country. Miss Florence Nightingale took up the question and succeeded in having a lying-in ward opened at King's College Hospital for the supply of material on which to instruct midwives. The juxtaposition of the lying-in cases with the wards containing pyæmia, &c., resulted in a terrible loss of maternal life and the ward had to be closed in 1867. I have already quoted the words used by this benevolent lady in her description of the Shorncliffe and Colchester maternities. About this time the higher education of women also began to be discussed and the first profession to which they tried to gain access was that of medicine, and after many years they succeeded as they eventually do in most matters. This question of sex militated against any progress being made in the different questions of the education of midwives, but in 1864 was started "the Female Obstetrical Society," its objects being: (1) to promote the employment of educated women in the practice of midwifery and the treatment of diseases of women and children; (2) to provide facilities for studying midwifery similar to those given to men; and (3) to establish a recognised board of examiners. At its second annual meeting a resolution was passed complaining of "the utterly unregulated state of female practitioners and the great public inconvenience and frequent loss of life which occurred for want of properly qualified and scientifically trained midwives." During the discussion Dr. Farr is reported to have said that "he believed that the medical profession, however, much as they might oppose female doctors would be glad to see educated young midwives take the place in every district of ignorant old women, and that he hoped to see the day when less than five women die out of every 1000 delivered of children." Dr. Farr's prophecy has been fulfilled.

In 1869 Dr. Farr suggested to the Obstetrical Society the investigation of the causes of infantile mortality, and a committee was appointed and a paper of questions was sent to each Fellow, whereby it was ascertained that "though in small towns the percentage of poor women attended by midwives was not more than 5 per cent. to 10 per cent.; in the large provincial towns and in the villages from 30 per cent. to 90 per cent. of the confinements were in the hands of women. Thus, for example, in East London 30 per cent. to 50 per cent. of the women had no doctor, and in the mining districts 90 per cent." (On comparing these returns with others obtained a few years ago by the Midwives Institute it seems that out of 4000 confinements 2500, or [illegible] were attended by midwives.) At this time [illegible] medical man was not required to qualify in midwifery and only a few examining bodies granted such diplomas and the profession was opposed to a partially qualified woman entering it. Dr. Farr had been for years continually calling attention in his letters in the Appendices of the Registrar-General's Reports to the excessive mortality from puerperal fever that was taking place. Dr. Farr observes: "The deaths by childbirth were 2275, besides 972 by metria in the zymotic class, [illegible] deaths in the aggregate. One mother died i[illegible] born alive." And the physician will, from the same facts, see how much art has to accomplish before the 3000 English mothers who perish annually in giving birth to their offspring can be spared. Natural and adventitious difficulties are in the way but they may in many cases be overcome, for "in sorrow" and not in death thou shalt bring forth children, that is the law of nature (fifteenth report). "The death of young women in child-bearing points to some of the dangers to be guarded against and many of the remaining dangers would be removed by a class of educated midwives" (seventeenth report). In the report of 1856 Dr. Farr presents matters as a little more hopeful and says: "The mortality in childbirth continues to decrease in England and Wales; the birth of every 10,000 living children was the death of 60 mothers in 1847 and of 44 in 1856; thus 16 are now saved in every 10,000 children born. This happy result encourages its cultivators to redouble their exertions" (nineteenth report). "This branch of medicine is cultivated in the present day with extraordinary zeal by men of superior quality; and a society recently has been formed for the cultivation of this important work" (twentieth report). Dr. Farr evidently refers to the formation of the Obstetrical Society. "Many men die of hernia, many women in childbed, who might have been saved by surgical skill" (twenty-seventh report). In the report for 1867 attention is called to (1) the infectious nature of puerperal fever; (2) its connexion with erysipelas and scarlet fever; and (3) to work in the dissecting room, &c., and to the deaths of child-bearing women in towns and country districts. "In towns they are more exposed to puerperal fever; in the country many probably perish from want of skilful help." "Nothing in England approaches the fatality of mothers in Wales, where they must be greatly mismanaged." Further on he refers to the discussion going on in medical circles on the excessive mortality in lying-in hospitals. "Cases in country are in the hands of midwives and men who are sometimes skilful by nature but often are not versed in the art as it is now practised by the skilful. Educated nurses as well as physicians are required to secure the best chance of life of mother and offspring" (thirtieth report). "Thus the contagion of scarlet fever in some cases lights up puerperal disease which has not yet been distinguished from puerperal fever. So does erysipelas and so perhaps do other diseases. The dangers of a general hospital to puerperal women have been revealed by recent experience. Students cannot study in the dissecting-room and at the same time practise midwifery without risk. Nurses are often the medium of the disease, nothing is more fatal than any of the forms of dirt and uncleanliness in the lying-in chamber. When fever comes on disinfectants should be strenuously used. By the greater attention this subject will attract now its full importance is precisely known we may hope to see a great diminution in the risks of childbirth." Here Dr. Farr refers to the closure of the lying-in ward at King's College Hospital and probably to the discovery of Semmelweiss (1847) and specially to the excessive mortality that was annually taking place in our lying-in hospitals. In this year Queen Charlotte's Lying-in Hospital had to be closed on account of an epidemic of a severe and fatal nature lasting for many months.

In 1868 the General Medical Council advised increasing the courses of lectures in midwifery at the various medical schools, so that every student should attend at least 20 cases, and, further, that they should have received instruction in the special diseases of women and children. In 1869 the Obstetrical Society did not actively take up the question of the education of midwives (because probably some of its prominent members believed all midwives to be a mistake and would be soon superseded by men) when Dr. Graily Hewitt spoke of the value of the society as a school of obstetric medicine and said, "It is indeed a question whether it be not the duty of the society to take steps for [illegible] e legislative enactment to check the licence [illegible] in relation to the employment of midwives, many of them quite unskilled and uneducated." About this time a school was established at Sir Patrick Dun's Hospital, Dublin, for the training of midwives attached to the regiments in the English army. This was a great success; six months' training was given, each midwife had to attend from 30 to 70 cases, to attend lectures, and to pass an examination. The establishment of this examination seems to have been a turning point in the whole matter. [illegible]0 the council of the Obstetrical Society passed a [illegible] in favour of the institution of a voluntary examination for midwives but it was not until 1872 that the scheme of such an examination was presented to the society and passed unanimously. The examination was "to consist of practical testing of the competency of the candidates to practise as midwives and the possession on their part of such an amount of knowledge as would enable them to recognise the presence of difficulties and the necessity for at once procuring competent professional aid for their patients."

In 1872 the General Medical Council passed two motions:—

> 1. That a committee be appointed to consider and report whether the General Medical Council has power to make rules for the special education of women, such as may entitle them to obtain a qualification to be certified by the Council and that the committee do report for that purpose whether such qualifications (if any) should be granted.
>
> 2. What are the most desirable means for educating, examining, [illegible] to them, wi[illegible] mid- [illegible] of medical [illegible] and [illegible]

In 1873 the above committee reported that the Council "had not the power to give qualification or to make a special examination for women"; it recommended that in any future Bill for the amendment of the Medical Act *a clause should be introduced giving power to the* Council to register the qualifications of women acting as midwives, dispensers, and superintendents of medical institutions. In the same year the council of the Obstetrical Society referred the matter of examination and registration of midwives to a committee which [illegible] "The Obstetrical Society of London havi[illegible] urgently brought before its notice [illegible] life and health occasioned by the practice of ignorant midwives has already institute[illegible] for testing the knowledge of women [illegible] calling of a midwife and has grant[illegible] who have satisfied the examiners." [illegible] Mr. Ernest Hart was asked by the [illegible] of the Local Government Board to draw up a scheme for the regulation and education of midwives. The matter was then brought before each separate branch of the British Medical Association and a subcommittee was appointed to consider and to modify, if it [illegible] scheme of the Obstetrical Society. In [illegible] eturn—"Laws and Regulations with [illegible] Abroad"—was obtained and this stimulate[illegible] In 1877 the Duke of Richmond's Med[illegible] use which purposed to legislate for the [illegible] ves in England and Wales but this portion of it was [illegible] ed, it might cause confusion between midwives and medical men. In 1882 a Bill was drafted by the British Medical Association but it was never presented to Parliament. In 1889 the General Medical Council resolved:—

> That this Council regards the absence of public provision for the [illegible] n of midwives as productive of a large amount [illegible] tal diseases among the poorer classes and urges [illegible] the importance of passing into law some measure for the education and registration of midwives.

The first Midwives Bill (1890) was promoted by the Midwives Institute, but it was withdrawn on the understanding that a select committee should be formed to consider the whole subject. This committee sat on several occasions but reported without hearing any evidence. The result was that a second Midwives Bill was introduced in

July, 1890, and this was reported to a select committee. In April, 1891, the Royal College of Physicians of London appointed a committee to consider this Bill and in the report which was issued the conviction was expressed that legislative action was desirable in order to secure the due education, examination, and registration of midwives and recommended that a Parliamentary subcommittee should be asked for before which the whole subject might be investigated. On June 17th, 1892, a select committee of the House of Commons reported as follows:—

[illegible]

In August, 1893, another similar committee reported thus:—

> [illegible] and have taken most valuable
> [illegible] t given last year at six sittings,
> [illegible] men and women in various
> [illegible] ountry, and also from trained

Lord Balfour introduced a Bill to the House of Lords in 1895. Then came the Midwives Bill of 1898 which followed the lines suggested by the select committee. By this time there was a consensus of opinion that reform could only be effected by legislation. Objections were raised to the Bill by certain members of the profession who urged that all pregnant women should be attended by medical practitioners and who held that no midwives should be created but be allowed to disappear gradually and that monthly nurses should be better trained and take the place of midwives. Others opposed the Bill as they believed it would lead to increase of abortion and infanticide and would endanger the lives of pregnant women and children and interfere with the training of the medical students to practise midwifery. This Bill, however, was not passed and it was followed by one in 1900 by Mr. Tatton Egerton, and the Midwives Bill 1902, which culminated in the Midwives Act 1902. The object of this Bill is "to secure the better training of midwives and to regulate their practice." It was brought in by Lord Cecil Manners, Mr. Tatton Egerton, Mr. Schwann, Mr. Parker Smith, Sir Savile Crossley, Mr. Eugene Wason, Mr. Tennant, and Mr. Heywood Johnstone. Evidence was given which fully proved that it was useless and impolitic to attempt to do away with midwives. It is not the midwives themselves that are to be blamed—it is the medical profession that should be blamed, *and I am always sorry when I hear* midwives maligned as "Gamps" and other disrespectful appellations, and although untrained, unskilled, and unconversant in the principles of aseptic and antiseptic measures as the majority of them are, yet I firmly believe that most of them have done their duty to the best of their skill and ability, and that they have rendered valuable aid to women in travail when medical assistance could not be got in time I can bear my personal testimony. It is clearly therefore our duty certainly not to malign them but to thank them for the good work they have done in the past and endeavour in the future to raise their status, for it will be better for them, for us, and certainly to our country at large. The half a million poor women who cannot afford medical aid in their labour, who are annually confined in England and Wales, I venture to speak for them, hail with delight the passing of the Midwives Act. On the other hand, it *must* be said that the late appearance of such an Act is partly due to the attitude assumed by midwives and to the unreasonableness of their own requests at one time. The *medical profession has for years been like a house divided* against itself on this question, the one portion making all endeavours to procure efficient instruction and training for midwives, the other taking equally strong measures toward their extinction. After a long time, however, the latter class seeing that the majority of their colleagues and the country at large would not do without midwives gave in, or shall I say were conquered, and it is to be sincerely hoped that all members of the profession will unite hands and efforts in making this Act a success throughout the land, especially in country districts.

THE MIDWIVES ACT, 1902.

This Act was passed on July 31st, 1902, and came into operation on April 1st, 1903. It does not apply to Scotland and Ireland. 1. The chief objects of the Act are: (*a*) to secure the *better training of midwives*; *and* (*b*) *to regulate* their practice.

Although one of the chief objects of the Act is to "secure the better training of midwives," yet neither the Act nor the rules *framed by the Central Midwives Board make any* provision whatever or even suggestions how this end may be attained and unless county councils and other local supervising authorities, or private benevolence, with or without the assistance of State funds, come to the rescue, I fear that, as was recently stated in THE LANCET by an experienced medical man, that "our midwives, though under control, will still for a long time be the worst trained and the most ignorant in Europe"; or, as Miss J. Wilson (a member of the Central Midwives Board) puts it: "This is not surprising when we remember the training abroad is not only thorough but is given practically free by the State or the *community*. The supply of candidates therefore in foreign countries presents no difficulty; a small but fixed salary is also guaranteed to the midwife in thinly-populated and remote districts and preference in training in some places is given to pupils who intend to practise among the poor. In England and Wales we must hope that private and public benevolence will take the place of State funds, with the advantage which seems essential to our national satisfaction—which is unknown in foreign countries—of combining voluntary interest with State control and effort. If, however, the work of training is to be adequate to meet the demand the subject should first receive careful preliminary discussion, deliberation, and forethought. Such work to be effectual should be undertaken as a national duty to meet a national need.

There are many schemes already before the public and I will only add mine as a foundation for debate. My views would run somewhat on these lines. I should like to see the formation of a national council for training, the principal functions of which would be to map out the country with a view to the best organisation for training and the provision for midwives, aided by local knowledge; to collect funds; to found training scholarships under approved conditions of binding midwifery probationers for a special period of work in poor districts; to utilise as far as possible our present hospitals; to give grants to districts to help to support a midwife; and, later, to found itself, or to help to support, a national maternity hospital in which the training should be on the best possible lines, specially for midwives for the poor. Considerable funds would be required and the undertaking should combine the best knowledge and experience available and should include the heads of those urban and rural maternity societies which have already done such invaluable work in training midwives for the service of the poor. In short, I should like to see such a council do for midwives' work in England and Wales what has been done in the United Kingdom for nursing by the Queen Victoria Jubilee Institute. I venture to express a hope that if such a council is formed it will not only train midwives but will arrange that their knowledge is maintained and improved. This is a most important part of the system abroad and it is desirable for the maintenance of a high standard of work."

Personally I am sanguine that the training of midwives will be undertaken by county councils and other public bodies. The late Dr. W. N. Thursfield put the matter in a nutshell when in 1893 he wrote: "Public bodies in various parts of the country are providing facilities for the technical training of women in almost every branch, from cooking to music. Training in obstetric nursing would, in some respects, be a typical form of technical training as it would be affording instruction of a kind otherwise out of the reach of those instructed and the skill acquired might be expected to supply a local need and find local employment. Efficient training in obstetric nursing cannot, however, be carried out locally in places most needing it, as to be efficient it must be at some institution where what would otherwise be the individual experience of a lifetime can be concentrated in the experience of a few weeks. Certainly in some way subsidies, to assist suitable women desirous of such training, ought to be forthcoming and if such provision is outside the province of public bodies here is an [illegible] e munificence of private philanthropy [illegible] county council has given to the Midwives Act considerable attention and has delegated its powers without restrictions to an executive subcommittee, with its medical officer as executive officer. The question of the training of midwives is now under the consideration of the education committee and I have reason to believe that a training centre or centres will be established, either by the county council alone or jointly with other bodies, for giving instruction to young women who desire to become midwives, provided they undertake to obtain the certificate of the Central Midwives Board and to practise for some time within the county, as many young women who may desire to take up this work may not be in a position to defray the expenses incurred. I am endeavouring to persuade my county council to include the training of midwives under the term technical instruction and to offer a few scholarships a year to encourage deserving young women to take up the work. With regard to the work of supervision, it is probable that a female inspector or inspectors will soon be appointed.

Many women, however, during recent years, anxious to become efficient midwives, have been trained at our lying-in institutions and elsewhere and have obtained certificates to the effect that they possess the knowledge necessary to fit them for their responsible work but before the passing of this Act it was permissible for any women with or without a good moral character and without having received any instruction whatever to undertake the conduct of any case together with the after-treatment of mother and infant. With a view of obtaining some guarantee that every woman who habitually and for gain practised as a midwife had received and profited by a regular prescribed course of training the Act was passed, chiefly in the interests of the poor. The kernel of the whole Act is contained in Sections 1 and 2 which may be summarised thus: (*a*) From and after April 1st, 1905, it will be illegal for any woman not being certified under the Act to style herself a midwife; (*b*) from and after April 1st, 1910, it will be illegal for any woman habitually and for gain to attend women in childbirth (otherwise than under the direction of a qualified medical practitioner) unless she is certified under the Act; and (*c*) up to the end of March, 1905, women holding certain certificates mentioned in the Act and approved by the Central Midwives Board may claim to be certified. Again, women who can satisfy the Central Midwives Board that they have been in practice for at least one year prior to July 31st, 1902, and that they bear a good character, may claim to be certified under the Act. Candidates not included in one of these classes will be required to pass the examination of the Central Midwives Board before obtaining a certificate.

2. The chief provisions of the Act are: (*a*) the constitution of a Central Midwives Board having certain powers and prescribed duties to perform; and (*b*) the constitution of local supervising authorities whose powers and duties are definitely stated. Provisions are also made for the punishment of offences under the Act and for appeal from any court of summary jurisdiction to the court of quarter sessions. The Central Midwives Board has been constituted and consists of five medical men, three ladies, and one Member of Parliament (appointed by the Association of County Councils).

3. The duties and powers of this Board are: (*a*) To frame rules—(1) regulating its own proceedings; (2) regulating the issue of certificates and the conditions of admission to the Roll of midwives; (3) regulating the course of training and the conduct of examinations and the remuneration of examiners; (4) regulating the admission to the Roll of women already in practice as midwives at the passing of the Act; (5) regulating, supervising, and restricting within due limits the practice of midwives; (6) deciding the conditions under which midwives may be suspended from practice; and (7) defining the particulars required to be given in any notice under Section 10 of the Act. (*b*) To appoint examiners. (*c*) To decide upon the places where and the times when, examinations shall be held. (*d*) To publish annually a Roll of midwives who have been duly certified under the Act. (*e*) To decide upon the removal from the Roll of the name of any midwife for disobeying the rules and regulations from time to time laid down under the Act by the Central Midwives Board or for other misconduct, and also to decide upon the restoration to the Roll of the name of any midwife so removed. (*f*) To issue and to cancel certificates. The Central Midwives Board has been formed according to the provisions of the Act, Section 3 (1), (2), (3), and rules under Section 3 (I.) have been framed and approved by the Privy Council for a period of three years.

The councils of a county or county borough throughout England and Wales become the local supervising authorities over midwives within the respective areas and their duties are: (1) to exercise general supervision over all midwives practising within their area; (2) to investigate charges of malpractice, negligence, or misconduct on the part of any midwife and, should a *primâ-facie* case be made out, to report to the Central Midwives Board; (3) to suspend any midwife from practice if such suspension appears necessary in order to prevent the spread of infection; (4) to report to the Central Midwives Board the name of any midwife convicted of an offence; (5) to supply the secretary of the Central Midwives Board with the names and addresses of all midwives who during the preceding year have notified their intention to practise and to keep a current copy of the Roll of midwives accessible at all reasonable times to public inspection; (6) to report to the Central Midwives Board the death of, or any change in the name and address of, any midwife; and (7) to give due notice of the effect of the Act to persons at present using the title of midwife.

With regard to the constitution of the Central Midwives Board I have one remark to make, and it is this: Would it not have been expedient to have nominated one person on this Board to represent the Incorporated Society of Medical Officers of Health, which in the past has rendered valuable services to the community in the prevention of disease and which in the future will probably be expected to advise as to the best methods of carrying into effect the various provisions of the Act? This is at least a matter worthy of further consideration. I am pleased that there are on this important Board three ladies whose sacrifices and efforts on behalf of the women of England and Wales are well known and that one person has been appointed to represent the Association of County Councils. According to Section 2 any woman who can satisfy the Board that she has been in *bonâ-fide* practice for one year before 31st July, 1902, can claim to be certified, provided that she bears a good character, and I fear that the majority[1] of our midwives will obtain their certificates in this way and among them many that are illiterate, unable to read to write, and to keep the necessary books and records much less to take the temperature, apply antiseptics &c , and perform other duties that will be required of them I feel sure that the Central Midwives Board, having no idea of how the question of the training of midwives would be taken up in the country at large, is experiencing a great difficulty in this connexion, anxious on the one hand not to admit any but competent persons to the Roll of midwives but on the other somewhat afraid that there would not be a sufficient supply of midwives up to 1910 Unquestionably this class of untrained midwife will form a serious problem in the working of the Act Individually many of them have done useful work but there are a large number whose self-confidence is only equalled by their ignorance Up to April 1st, 1905, *any* woman may practise as a midwife but after this date *no* woman shall be allowed to call herself a midwife or any name suggesting competence unless she has earned it by training and obtained an acknowledged certificate, but she will be able to practise with impunity up to April 1st, 1910

Then the final step comes into operation for from April 1st 1910 no woman uncertified under the Act shall habitually and for gain attend women in childbirth, excepting as the friendly assistant in emergency We have therefore the period from now to 1910 (six years) as pointed out by Mrs Heywood Johnstone in which "to review the whole situation and prepare for the change so that, when the 'Gamp and all her train of death sorrow, and suffering passes from our midst, the dawn of a better state of things shall culminate in a sufficient supply of trained midwives who have been taught to care for mother and infant and who will be bound to call in the doctor in cases of disease and abnormality before they have drifted beyond the reach of medical skill The untrained midwives (and excellent women some of them are) will ere this has elapsed have rapidly decreased in number or passed away and the younger ones will either get the requisite training or not care to take up a profession so soon to be condemned Mrs Heywood Johnstone further observes 'Are we creating a vacuum ? Are we to let the law become a dead letter ? Shall the labour of those who have toiled so hard become void, or worse than void in a *new form* of suffering to the poor women who cannot afford and yet imperatively need, assistance in their confinements ?' The same lady further says I am sure it will not be so " Indeed I am not at all sure that it will not be so unless the matter is strongly and prominently brought before county councils and other authorities by medical officers of health and others having at heart the interests of our poor women Doubtless in the case of the 26 county councils and a large number of county borough councils this will be the case but what about the remaining county councils which have not appointed medical officers of health to advise them in these and similar matters ? and, above all, what about the small district councils ? The horizon is very dark and at present I cannot detect a silver lining to it I am aware that great activity has been aroused in some quarters regarding the important questions of the training of midwives and that the number of trained midwives are increasing rapidly, not to speak of district nursing associations that are multiplying throughout the country where poor women can obtain the combined assistance of nurse and medical man

I agree with the suggestion of the Central Midwives Board that a few women conversant with the need of the poor of districts in question should be on every local supervising authority and it is with their aid that we can hope to accomplish what we have in view, for it is within their power to render substantial public service by preparing themselves for the work and combining experience, tact and sympathy with a sense of public duty Much remains to be done "Organisation is necessary that we may bring together the women that wish to be trained the institutions competent to train them and the many parishes crying out for help that do not know how to manage and organise and in some instances sorely need pecuniary assistance A thorough enquiry should be made in each county that we may know what foundations we have to work upon and this should be followed by suggestions and consultations as to the best means to give practical help in all these details and for this I cannot emphasise too strongly how important it is to obtain assistance of those experienced both in the training and the supply of midwives and in the needs of the poor especially the rural poor I have made such inquiries in the administrative county of Glamorgan with the following results —

Number of midwives	about 700
trained midwives	70
Percentage of confinements attended by midwives in colliery districts	80 per cent in mining districts
Deaths in childbirth	53 in 1902
Institutions where midwives may be trained	None except Cardiff union infirmary
Infant mortality rate	Very high average for 1892 1902 = 188 per 1000 births
Early marriages	This is the rule in the mining districts

I now come to the question of the constitution of local supervising authorities and the duties they are expected to perform According to Section 8 county and county borough councils are the local supervising authorities, but according to Section 9 they may delegate their powers (with or without restrictions or conditions) to 1 A committee appointed by them and consisting either wholly or partly of members of the council (and the provisions of subsections 1 and 2 of Section 82 of the Local Government Act 1888 shall apply to every committee appointed under this section and to every council appointing the same and women shall be eligible to serve on any such committees) 2 District councils I am in full agreement with the following "suggestions to county and county borough councils recently issued by the Central Midwives Board, viz —

> 1 The Central Midwives Board suggests to the county councils the advisability of *retaining* the administrative duties assigned to them under the Midwives Act 1902, as far as possible in the hands of a committee directly appointed by themselves This will not only secure for the county council more adequate control over the expenditure but will tend also to prevent the possibility of local rivalries and jealousies interfering with the carrying out of the provisions of the Act
>
> 2 The Board suggests further that the health committee of the county council would form a suitable committee to act as the local supervising authority with power to add to its number from outside the council or otherwise In counties where no county medical officers of health have been appointed it is suggested that a special
>
> it may appoint one or more women conversant with the needs of the poor of the district

I agree that where the county council has already appointed a medical officer of health this officer should be the person to advise the county council in this matter for the supervision required is rightly regarded as at least in part a medical duty I further agree that this committee should be constituted as suggested With regard to counties where there are no county medical officers it is suggested that a special medical adviser be appointed to advise the committee Such a suggestion is very vague and it must have been most difficult for the Board to have made any suggestion at all Who is the medical adviser to be and what must be his qualifications ? Is he to be one of the medical officers of health within the county ? We are not told but I am of opinion that great difficulties will be experienced in persuading county councils to appoint such an officer and I am also of opinion that it would be undesirable and impolitic to appoint a medical officer of health who is also in practice, for such an arrangement would be likely to lead to difficulties arising through friction with his colleagues Where there are whole time medical officers of health in a county it appears to me that such a person or persons should be appointed medical adviser or advisers A county council is not bound to appoint a medical adviser and if it does not the carrying out of the Act must be left to the district councils of the area

I am strongly of opinion that none of the administrative powers conferred on county councils by this Act should be delegated to district councils for the following amongst other reasons 1 If the county councils delegated their powe[illegible] district councils and [illegible] be difficult, if not [illegible] powers and duties are delegated the medical officers of health would probably be the executive officers to these district councils, and it appears very undesirable that he or they (if also in general practice) should in his own district and amongst his own patients be the censor of the conduct and capabilities of the midwives within the area. For a similar reason it seems undesirable that district councils should be called upon to investigate charges of malpractice, negligence, or misconduct, or to suspend any midwife from practice. Many shades of opinion would be imported into every inquiry and it would be difficult to exclude the influence of personal feeling and bias. 3. It is most desirable that the Act should be administered with the greatest uniformity possible, but if the powers and duties are delegated to district councils this end would not be secured. 4. Further, it must be borne in mind that any expenses incurred by a district council in the execution of any powers or duties delegated to them under the Act, shall, to any amount not exceeding such sum as may be prescribed by the county council, be repaid to such district council as a debt by the county council, and until the Act has been in operation for some time it will be impossible for the county council to estimate with any accuracy the expenses incurred in a given district.

---

[1] At the end of January 1904 the total number enrolled by the Central Midwives Board was 1600, of these 1079 were *bonâ fide*

The midwife is permitted to attend normal labours only and in every emergency she is compelled to send for a qualified medical practitioner, and as everything will depend on her ability to recognise in time any danger and abnormality in either mother or child it is very important for her training to be thoroughly efficient. It is the duty of the Central Board to regulate the course of training and the conduct of examinations. As Dr. W. J. Sinclair has remarked: "A midwife must no longer trifle with a woman's life or health because she hopes that some vaguely comprehended abnormality may right itself without help or because she fears to expose her ignorance to *the medical practitioner and to the family of her client.* She will find it injurious to her interests to temporise with puerperal sepsis until the patient is moribund, or at least beyond the reach of therapeutic measures; she will not dare to conceal the worst injuries of parturition until remote operations are rendered necessary; she will no longer treat ophthalmia of the new born until the infant must inevitably become blind or give frivolous advice with regard to skin affections which signify a fatal or a curable malady according to the time and method of treatment."

The Central Midwives Board has power to cancel as well as to issue certificates. "No woman certified under this Act shall employ an uncertified woman as her substitute." This is a much needed reform and it entirely forbids the practice of employing substitutes in any shape or form, and will put an end to the abuse of employing ignorant women to do the nursing after the labour is over.

The midwife of the future will not be authorised to grant any medical certificate or any certificate respecting the stillborn. The question of the registration of stillbirths has long been ripe for discussion. The Registration of Births and Deaths Act, 1874, permitted burials of stillborn children to be carried out on the declaration of a midwife or any other person present at the birth. This has undoubtedly led to much social scandal and a fruitful source of undetected crime. The number of stillbirths is at present unknown, but in future the midwife's record must show the number of these cases, and in this way the number occurring in a certain area can be ascertained. Stillborn children are too easily disposed of and many evils and irregular practices are hidden which ought to be investigated. The deaths, stillbirths, and cases of puerperal fever and other infectious disease must be notified to the local supervising authority. No midwife shall undertake the duty of laying out the dead or follow any occupation that is in its nature liable to be a source of infection. The local supervising authority should therefore be thoroughly conversant with the homes of all their midwives and the work which they undertake between cases.

The duty of reporting to the local medical officer of health any notifiable disease rests with the medical attendant as heretofore. It is most desirable also that the medical attendant should be compelled to make a similar notification, on the payment of a reasonable fee, *at once* to the medical adviser [illegible] rity, because this is the only [illegible] officer can obtain the informati[illegible] obtained promptly it is of but little use. In the county of Glamorgan, through the courtesy of the local medical officers of health, I receive weekly notifications, but they are not compelled by law to supply this information. The records of the midwife will show the number of fever cases which have occurred in her practice and the name of the medical man who assisted her; they will show the past record of parturient women should such information be required on some future occasion and the midwife must send a copy of this record to the executive officer. After attendance upon a patient suffering from puerperal fever or other infectious illness the midwife must disinfect herself and her appliances, and have her clothing thoroughly disinfected before going to another case. The local supervising authority may suspend a midwife if such suspension appears necessary to prevent the spread of disease. I consider it desirable that the medical adviser should be empowered by the committee to act promptly and at his discretion in a matter where immediate action is imperative. In Sweden a midwife must abstain from practice for a week after attending puerperal fever and live as much as possible in the open air. I consider that the question of the disinfection of midwives, their clothes, and their appliances is of the utmost importance and that no one should be certified unless they have a thorough practical knowledge of what disinfection means. I hope very shortly to see every sanitary district or groups of districts in Glamorgan supplied with isolation hospitals and in connexion with each such hospital the sanitary committee has insisted on having (1) an efficient disinfecting apparatus and (2) a discharging block, where without coming near any of the nursing staff or patient in the hospital it can [illegible] midwife can have a disinfecting bath. [illegible] trace several cases of puerperal fever to the neglect of disinfecting soiled beds and bedding by local authorities, and I am speaking definitely when I say that disinfection is at the present undertaken in a very half-hearted and deficient manner by some sanitary *authorities.*

A candidate for the certificate of the Central Midwives Board must have reached a sufficient standard of general education to enable her to keep the books and to prepare the records required of her. She must be not under 21 and not over 35 years of age, must have undergone a certain training, and produce a certificate of good moral character. As to training required she must have, under satisfactory supervision, attended and watched the progress of not fewer than 20 labours, making abdominal and vaginal examination during the course of labour and personally delivering the patient. She must have nursed 20 lying-in women during the ten days following labour. She must have attended a sufficient course of instruction and pass an examination, partly written and partly oral, in: 1. The elementary anatomy of the female pelvis and generative organs. 2. Pregnancy and its principal complications, including abortion. 3. The symptoms, mechanism, course, and management of natural labour. 4. The signs that a labour is abnormal. 5. Hæmorrhage, its varieties and treatment of each. 6. Antiseptics in midwifery and the way to prepare and to use them. 7. The management of the puerperal patient, including the use of the clinical thermometer and the catheter. 8. The management (including the feeding) of infants and the signs of the important diseases which they may develop during the first ten days. 9. The duties of the midwife as described in the regulations. 10. Obstetric emergencies and how the midwife should deal with them until the arrival of the medical man. This will include some knowledge of the drugs commonly needed in such cases and the mode of their administration. 11. Puerperal fever, its nature, causes, and symptoms; the elements of house sanitation; the disinfection of person, clothing, and appliances. She must also show acquaintance with the ordinary subjects of elementary education.

With regard to the use of drugs there exists a great difference of opinion but the rules state that she "must enter in a book all the occasions on which she is under the necessity of administering any drug, whether scheduled as a poison or not, the dose, and the time, and cause of its administration." I am very doubtful whether such drugs as opium, morphine, and others should be placed at the discretion of thousands of unqualified persons who are only certified for attendance on normal cases of labour, involving the safety of the public. To possess some knowledge of house sanitation is very necessary, for midwives conversant with the elements of hygiene and the meaning of antiseptic and aseptic precautions will be able to render help to their patients in putting in order their houses, especially the lying-in room. They will be able to teach the value of personal cleanliness and doubtless their work in promoting reform in these directions will have a wide and wholesome influence. "Interest has been recently manifested by the activity of many Members of Parliament by the introduction of projects for remedial legislation and by the work of many associations, and I think it is not too much to hope that indirectly the silent work of educated midwives will prove a wholesome stimulus to the higher classes of society and arouse their sympathy in the great work of improving the dwelling-houses of the labouring classes of our country."

The practical work—i.e., attendance on labour, &c.—must be done under the supervision of a registered medical practitioner or by the chief midwife of institutions recognised by the Board. The certificate to the effect that the applicant has been in *bonâ-fide* practice for at least 12 months prior to July 31st, 1902, and that she is trustworthy, sober, and of good moral character, must be signed by a justice of the peace, minister of religion, registered medical practitioner, or other person acceptable to the Board. I venture to suggest that such a certificate should be signed by two persons, one of whom *must* be a registered medical practitioner.

In the directions to midwives it will be seen: 1. No midwife shall undertake the duty of laying out the dead or follow any occupation that is in its nature liable to be a source of infection. I take it that the last sentence includes the nursing of persons suffering from erysipelas, septicæmia, infectious disease, &c. The duty of enforcing such a clause devolves on the local supervising authorities and there will be a great scope for doing efficient work in this direction. 2. Every midwife must enter in a book particulars of all drugs she uses. 3 She must send for the medical man at once in all cases of abortion, illness of patient or child, or [illegible] during pregnancy, labour, or [illegible] important technical knowledge [illegible] detect these conditions, and hence the value of the required training. 4. Every midwife sending for a registered medical practitioner must state in writing the conditions of the patient and the reason of the necessity for advice. 5. When the death of mother or child or a stillbirth occurs where a registered medical practitioner is not in attendance the midwife shall as soon as possible after the occurrence report to the local supervising authority. It would be wise to insist before admitting any woman to the roll of certified midwives that she has been properly vaccinated.

The records that midwives must keep include: (1) a register of cases; (2) the occasions of sending for medical help; and (3) a case-book with further detail. A copy of (2) must be sent to the local supervising authority within 12 hours. Such records will be most useful for further reference and may be the means of enabling the midwife or the medical attendant to prevent at some future confinement some of the "accidents of childbirth" in the parturient which frequently end fatally.

Regarding the duties of the local sanitary authority the rules read thus: "Whenever a midwife has been in attend- [illegible] from any [illegible] t disinfect [illegible]es to the [illegible] must have [illegible] to another [illegible]pervising [illegible]oiled and [illegible] (by the local sanitary authority) and then exposed to the open air for several days." The difficulty of disinfection will be a serious one in many rural districts in agricultural counties where means for disinfection and isolation have yet to be provided.

[illegible]

ON DIABETIC NEURITIS.

BY F. W. PAVY, M.D. LOND., LL.D. GLASG., F.R.S.,

CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

(Concluded from p. 19)

BESIDES motor and sensory filaments nerves contain filaments belonging to the vaso-motor system and these may become involved in the morbid state appertaining to neuritis. In this way an effect may be produced upon the vascular system, leading to the contractility of the vessels being thrown out of proper working order. Hence the occurrence of local flushings and pallor of an abnormal nature. As a result the hands or feet may become at times hot and florid from dilated vessels or blanched and cold from contraction taking the place of dilatation. Naturally the vessels adjust themselves to the altered positions assumed by a part so that an equable state is maintained whether the limb is held up or hung down, but under a loss of proper vaso-motor nerve power the vessels in the one case may become unduly emptied and in the other unduly distended. Local areas of sweating, referable assumedly to an altered vascular state, are, it may further be mentioned, sometimes noticeable.

Nutritional disordered action is well known to arise from [illegible] secondarily. Besides altered nutrition dependent upon an altered state of the blood-vessels nutritive aberration may arise from the direct effect of loss of the influence of nerve [illegible] tissues. [illegible] of a trophic [illegible] diabetes and [illegible]ith peripheral [illegible]er extremities exists the feet of the diabetic are placed in an exceptionally vulnerable position. A very [illegible] to the establishment of ser[illegible] a more or less extensive loss [illegible] even the loss of life. A nota[illegible] the pain with agonising exacerbations that is ordinarily experienced in the affected part. The pain is out of proportion to what would be looked for simply from the destructive process proceeding but in conformity, it may be said, with the co-existence of peripheral neuritis. There are points of alliance between the condition to which I am alluding and Raynaud's disease and in connexion with the latter authorities believe that neuritis constitutes a factor.

Another trophic lesion is [illegible] from time to time is met wi[illegible] diabetes. A spot of surface [illegible] and remains without exhibiting any sign of healing action. An incrustation may form under which ulceration may proceed and by-and-by a burrowing sinus may be discovered leading, it may be, into the joint of a toe or to denuded bone. Sometimes this condition is attended with such little surface appearance as to lead to surprise being experienced [illegible] has advanced [illegible]ain restricted [illegible]s the requisite healing power to become reinstated and the sore persists in an indolent state. There is usually a prolonged history of peripheral neuritis. For the sake of illustration I may allude to the following cases. A diabetic patient, aged 50 years, who had been for some time the subject of peripheral [illegible] himself with an [illegible] of each great toe [illegible]e, aged 63 years, [illegible]rs and had become [illegible]me with her urine [illegible] passed was very [illegible] the actual amount of sugar [illegible]1 per 1000. This [illegible]ngs was not to be wondered at as she had [illegible] Mellin's food. Upon [illegible] and in addition [illegible]ich she suffered [illegible]ng and stinging pain.

[illegible]n referring to trophic conditions arising from diabetic neuritis but trophic lesions occur also in connexion with diabetes as a primary result of the effect of the sugar abnormally passing through the system. By virtue of the abnormal presence of sugar in the system the nutritive operations are interfered with and various trophic disordered states produced. Amongst these mention may be made of cataract, loosening of the teeth, certain dermatoses including xanthoma diabeticorum, boils, and carbuncles. Indeed, diabetic neuritis is itself a primary trophic lesion due to the effects of the sugar in the system, from which also the textures generally of the body to a greater or less degree suffer.

Diabetic neuritis is a very variable affection with respect to location. Most commonly, as with other forms of neuritis arising from a toxic agency, its development exhibits a symmetrical character. The lower limbs are observed to suffer far more frequently than the upper. The upper and lower may be more or less affected together and somewhat exceptionally the upper may be attacked without any symptoms being experienced in the lower. I have a record before me of a case in which the right leg, the right side of the body, and the right arm as low as the elbow were the seat of neuritic pains without anything wrong on the left side being complained of. The patient, aged 66 years, had been the subject of diabetes for five years and the urine at the time to which I am alluding contained 38 per 1000 of sugar. Sometimes the neuritis is localised to a particular nerve. Sciatica often occurs in connexion with diabetes. It is true, it may perchance happen that the sciatica met with in the diabetic may be consecutive as in other cases to cold or some other incidental exciting cause, but at the same time the sugar in the system may contribute to the production of an increased susceptibility to the influence of the exciting cause and thus render the person more than ordinarily liable to the occurrence of the affection. The brachial nerve may similarly suffer and in each case, if the lesion be severe and lasting, more or less wasting of the muscles involved may be noticed to occur.

Looking at the circumstances existing it is not surprising that we should have a protean class of symptoms to deal with in diabetic neuritis. I have seen cases where the main *seat of trouble has been in the abdominal region.* For example, a patient, aged 67 years, who had been the subject of diabetes for 11 years complained of the frequent occurrence of lancinating or "lightning" pains on the right side of the waist. In addition there existed a tingling sensation in the skin accompanied with hyperæsthesia. I may also cite the case of a patient, a female, aged 58 years, who had been diabetic for five years. The symptoms here were very marked and the urine contained when the patient was first seen by me 41 per 1000 of sugar. The pain was mainly on the left side of the waist. Besides more or less continuous pain frequent sharp flashing pains occurred which were sometimes so severe as to cause the patient to start up and in a moment they were gone. The flesh felt sore and often with a sensation as though the ribs were piercing into it. The skin was acutely tender, so much so that the patient could not bear the crease or the gather of an undergarment against it and was in the habit of placing a silk handkerchief evenly folded over it, whilst the corset required to be worn very loose and sometimes to be removed during the day for obtaining relief from the distress experienced. A smarting burning sensation was another symptom that was frequently experienced, especially when the skin was exposed to the air as in undressing. If suddenly startled by anything a painful sensation immediately darted through the affected part. The legs participated to a minor degree in the neuritic trouble, there being a certain amount of ataxic gait and of sensory disturbance. In the treatment of the case great help was afforded by the continuous galvanic current.

Some few cases have fallen under my notice where anginal symptoms have existed in connexion with diabetes and I have been led to consider that they have arisen from neuritis having attacked the pneumogastric nerves. I thought very seriously of the condition when it first presented itself to my notice but experience has since impressed me with a different view. I have known the cardiac distress to be such as to cause the patient to pull up suddenly in walking and to feel that danger of impending death existed. In one case temporary vomiting at times accompanied the cardiac pain that came on when walking, a circumstance which brought to my mind the joint anatomical connexion of the pneumogastrics with the stomach and the heart. I have found that the condition has sooner or later yielded to diabetic treatment and notwithstanding the threatening aspect that the case may have presented I have not known any bad result to occur. I may further mention that I have seen a few cases of the third nerve being the seat of neuritis with the attendant symptoms of dropped lid and external squint. There being other causes producing this affection it must not hastily be concluded because it happens to occur in a diabetic that it is therefore due to diabetes. It is known, however, to arise from the effect of toxic agencies and this affords *a priori* ground for assuming that it may occur as a result of diabetes. Should evidence be presented of the existence of neuritis elsewhere support may be considered to be given to the local affection under consideration constituting a result of the diabetes, and thence being less serious than might otherwise perhaps be apprehended.

I have spoken of the varied manifestations of disordered action that may present themselves as a result of peripheral neuritis accompanying diabetes and I will now refer to the pathological source of the nerve lesion. Peripheral neuritis, as is well known, is associated with a variety of conditions in which a toxic agent stands as the operative factor. The toxic agent may reach the system from without as with alcohol, lead, arsenic, &c., or be developed within as with the toxins produced in connexion with diphtheria, variola, septicæmia, and some other diseases. Diabetic neuritis is set down in works dealing with the subject to the effect of a toxic agent. I do not question the correctness of this view, but, owing to conclusions based upon misleading evidence, a wrong idea, I consider, has been broached regarding the nature of the agent. In Ross and Bury's work on Peripheral Neuritis at p. 374, where diabetic neuritis is under consideration, there appears the following statement: "All writers on the subject agree that the neuritis does not bear any relation to the amount of sugar in the urine. In many of the cases recorded the amount of sugar has been small: in a case reported by Burns not quite 1 per cent., and in another case between 1 and 2 per cent. Further, the symptoms continue if by strict diet the sugar can be made to disappear from the urine. The above facts seem to indicate that the neuritis is not due to the presence of an excess of sugar in the blood." Such is the groundwork upon which the view has found currency and in a stereotyped way appears in books that the sugar in the system is not the cause of diabetic neuritis. It is further asserted that the neuritis is not attributable to the acetone series of products that often accompany the sugar and to get over the difficulty presented some unknown toxic principle developed in connexion with the diabetes has been brought in and regarded as the morbific agent.

My experience is diametrically opposed to the allegation that has been made acquitting the sugar; and in saying this I am fortified by the ample means for forming a judgment afforded by the frequency with which neuritis occurs in connexion with diabetes. The frequency, it is true, is not equally distributed throughout the field of observation. In the classical form of the disease occurring in young subjects and running a comparatively rapid course, whether from the nerves being less vulnerable to attack or whether from the more limited duration of the condition, neuritis, certainly of a definite nature, may be spoken of as being but rarely seen. In the chronic type of case, however, at middle and advanced age, where the sugar is not kept properly under control it is seldom that the patient goes on for any great length of time without becoming affected with symptoms in some form or other of neuritis. That the products belonging to the acetone series stand outside the question is shown by the occurrence of the neuritis without the products being present. Indeed, it is especially in connexion with the lighter or "alimentary" form of diabetes, the form that is unattended with the presence of the acetone series, that neuritis is particularly found to occur. The converse condition also is often noticed and may be taken for what it is worth. The "composite" class of case, the one in which the acetone group of products is present, is the one in which neuritis is the less likely to be met with. With respect to sugar, this is invariably present in connexion with the supervention of diabetic neuritis. I do not know of such a thing as the supervention of diabetic neuritis in cases where the sugar has been successfully kept under control by dietetic management, although the case may have run on for years. Touching the statement made in the passage quoted regarding the existence of neuritis with the absence of sugar there is a point that requires to be borne in mind.

In the "alimentary" type of the disease the sugar is susceptible of being very speedily and markedly influenced by food The cases upon which reliance has been placed for assuming that sugar is not an essential factor in connexion with the production of neuritis may be taken, I consider, from my experience, to be cases in which the recorded state of the urine failed to represent the state existing at the time the production of the nerve lesion occurred The nerve lesion having become established it cannot undergo a sudden subsidence but the condition of the urine may be rapidly altered and therefore when the analytical examination is made it may simply through the instrumentality of food contain only a little or even no sugar, whilst previously there may have been a large amount In the presence of these circumstances it is easy for an erroneous conclusion to be arrived at unless the observer should be specially on his guard against it

Whilst writing these remarks a case in point has happened to fall under my notice The patient, a man, 63 years of age, had been the subject of diabetes for nine years The onset of the disease was somewhat sharp and severe but by treatment the symptoms became subdued and the patient afterwards continued in a fairly satisfactory state till about a year ago when he began to grow thinner and subsequently noticed, according to his statement to me, that he was at one period passing about a gallon of urine a day He afterwards became the subject of distressing pains and sought medical advice Dieting was resorted to and opium was administered The diabetic symptoms subsided but the pains continued and at this stage I saw the patient through an appointment made by his medical attendant I found that pronounced and very characteristic symptoms of peripheral neuritis existed Night and morning specimens of urine were brought for examination and on these being tested the night specimen gave only a traceable indication of the presence of sugar and the morning specimen none This is by no means the only instance I could relate where diabetic neuritis has existed and adequate sugar has failed to be found in the urine at the time of consultation to account for it From what has preceded it is easy to understand that the event is not an unlikely one to happen

As regards the continuance of symptoms after the sugar has been made to disappear from the urine by the restricted diet—a point advanced against the proposition ascribing the neuritis to the sugar—there is really nothing observable but what might be naturally looked for under the view that the sugar is the causative medium and therefore no necessity to bring into the question the effect of an unknown agent As I have already stated, neuritis does not occur in cases where the sugar is kept under by treatment In cases in which it does occur it goes hand in hand with the sugar but a certain time is necessarily needed when the nerve lesion has become established for it to subside after the disappearance of sugar has been effected The more fixed or deeply rooted the condition the longer it may reasonably be expected will be the time required For relief the getting down of the sugar constitutes an essential matter and when the latter is attained the former may be predicted more or less speedily to follow Recovery having taken place the maintenance of a satisfactory state may be looked for as long as things are kept right as regards the sugar but if the sugar should be allowed to return a relapse is not unlikely to occur A close parallelism exists between alcoholic and diabetic neuritis and in the latter sugar, I consider, may be looked upon as holding the position held by alcohol in connexion with the former

Diabetic neuritis is satisfactorily amenable to treatment if the requisite measures are fully carried out The first and chief point to be attended to is by appropriate dieting to remove or reduce the sugar which is at the foundation of the abnormal nerve state Without the accomplishment of this it is futile to expect that hopes can be entertained of any fruitful result occurring Where, however, the desired object has been attained it is sometimes surprising to see the rapidity with which improvement sets in Much, of course depends upon the extent to which mischief has advanced and the length of time it has existed Frequently I have noticed a few days suffice for comparative ease to take the place of a pre existing state of painful distress Usually in a week or two it may be reckoned that relief from actual bodily suffering will be obtained, but it may take time for the minor symptoms of the neuritis to disappear Exceptionally it may be found that obstinate resistance of some duration is met with and great distress may meanwhile be experienced Conjoined with the dietetic and codeina or opium treatment for the diabetes I have been in the habit of administering with a beneficial effect five grains of the iodide of potassium and ten grains of bromide of ammonium in a suitable vehicle three times daily In the few cases that have failed to yield to these measures I have had recourse with a satisfactory result to the galvanic continuous current Where great superficial pain has existed I have seen benefit conferred by the cautious application of the linimentum aconiti

PATHOLOGICAL SUGGESTIONS.

(1) THE PREPARATION OF MICROSCOPIC SLIDES FOR BLOOD-FILMS, (2) THE POSSIBLE APPLICATION OF FORMALIN GELATIN AS AN ANTISEPTIC AND DISINFECTANT PROTECTIVE SKIN, AND (3) A TRYPANOSOME-LIKE ORGANISM FOUND IN ASSOCIATION WITH SOME CHRONIC PATHOLOGICAL AFFECTION OF THE MOUTH

By A E WRIGHT, M D Dub, .
LATE PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY, PATHOLOGIST TO ST MARY'S HOSPITAL, PADDINGTON, W

(From the Pathological Laboratory, St Mary's Hospital)

1 *On a simple method of preparing microscopic slides for blood-films* —The frequent disappointment, inconvenience, and loss of time entailed upon the microscopic workers by improperly prepared blood films will perhaps justify the publication of a brief note upon a very simple method of getting over the difficulty which arises when the blood which has been spread out upon the slide runs together in such a manner as to leave a system of islands of piled up corpuscles ringed round with spaces of uncovered glass Such running together of the corpuscles, which is currently and superstitiously imputed to the grease on the slide, is simply referable to the smoothness of the surface It can, as I have elsewhere taken the occasion to point out, be remedied by etching into the surface of the glass with a strong caustic alkali or other corrosive chemical

This method of getting over the difficulty involves, however, access to chemicals, the use of a laboratory, and, above all, troublesome forethought All this is unnecessary I now find that the finely roughened surface which is required for the preparation of ideally perfect blood films can be very simply and unlaboriously obtained by rubbing the surface of the slide with emery paper I have employed the finest variety of emery paper and have, in order to obtain the necessary mechanical pressure, mounted the emery paper by means of a rubber ring upon a stout cylindrical ruler In making a film a drop of blood is placed upon a slide thus prepared, another slide is brought down upon it, and as soon as the blood has spread out in the included angle the upper slide is gently drawn along the surface of the lower. The upper slide is held at an acute angle with the lower where a very thin film is to be obtained, at a larger angle where a thicker film is desired

In view of the circumstance that the disc shaped and smaller spherical elements—red corpuscles and lymphocytes respectively—slip easily under the slide when the larger spherical elements—mononuclear and polynuclear white corpuscles—are carried onwards and outwards to the edges and end of the preparation films made as described are ill adapted —unless where certain precautions are observed—for the purposes of a differential count of white corpuscles Where such differential count is desired a line should be ruled with a needle longitudinally from end to end through the equatorial region of the film, and the count should proceed from one end of the equator to the other

2 *On the possible application of formalin gelatin as an antiseptic and disinfectant protective skin* —The fact that solutions of gelatin set into a firm, insoluble, and elastic jelly on the addition of formalin is, if I mistake not, capable of being turned to manifold practical account Taking a 15 to 20 per cent gelatin, liquefying it by the application of heat, making to it an addition of from 1 to 2 per cent formalin and employing it immediately after mixture we obtain a preparation which, when painted over a moist surface, will adhere firmly to it forming a

tenacious, elastic, and insoluble skin. Such a skin is, I think, admirably adapted to the arrest of hæmorrhagic oozing. I have employed it for this purpose with very satisfactory results, painting it upon the gums in a case of hæmophilia where bleeding had persisted for weeks in spite of the local application of adrenalin chloride and ferric chloride.

The formalin gelatin finds, however, its most generally useful application when it furnishes a protective antiseptic skin to denuded surfaces. It furnishes here an antiseptic and insoluble coating which protects the underlying tissues and is not removed by ordinary washing.

Again, inasmuch as pyogenic micro-organisms (staphylococci) have in the experiments I have carried out been rapidly devitalised when imprisoned under a skin of formalin gelatin, it would seem possible that this material may render services to the operating surgeon. Painted upon the skin it might conceivably furnish the aseptic surface which is required. Conceivably the surgeon might carry his incisions through such a film. Again formalin gelatin might prove useful in sealing up operation wounds, especially operation wounds of mucous surfaces.

Where employing the formalin gelatin upon a denuded surface, pain is avoided by applying first a film of simple gelatin and coating this over when dry with the formalin gelatin. When proceeding thus a tube of sterilised gelatin is melted in hot water and applied to the wound with a brush. This done a volume of formalin equivalent to a twentieth of the bulk is added to the remaining liquid gelatin. The 2 per cent. formalin gelatin thus formed must be applied before it has time to set.

3 [illegible] *anism found in association with* [illegible] *fections of the mouth.*—The atten[illegible] observers being for the moment focussed upon the study of the life-history and pathological significance of trypanosomata and allied forms it is perhaps opportune to point out that suitable material for the investigation of these problems may perhaps lie ready to hand. I have in view pyorrhœa alveolaris and other chronic affections of the mouth and the micro-organisms which have been described by French bacteriologists, and in particular by Vincent, under the names of bacillus fusiformis (or hastilis) and spirillum buccæ. The micro-organism denoted by the name of bacillus fusiformis is, I think, clearly not of bacillary nature. Judging from its size (ranging sometimes up to 20 μ), its staining reactions with Leishman's stain (blue staining of the protoplasm and development of three or four chromatin bodies stained red in a characteristic manner), and from the fact that it moves actively through a hanging-drop preparation with an eel-like undulatory movement, the micro-organism would, in spite of the apparent absence of undulatory membrane and flagellum, appear to have affinities with a trypanosome. The resemblance to a trypanosome is heightened when the organism is seen ploughing its way through the corpuscles of a drop of added blood. The micro-organism denoted by the name of the spirillum buccæ is practically always found in association with the above. I have, however, failed to find it in one of three cases of chronic mouth affections in which the so-called bacillus fusiformis has been present in large numbers. The spirillum buccæ as seen under the microscope in a moist film executes incessant whip-like movements which bring up vividly to mind the lashings of the flagellate body in malarial blood. The spirilla here in question do not take the stain deeply when treated with watery solutions of basic aniline dyes.

It may be stated that neither of the above-mentioned forms of micro-organisms has as yet been artificially cultivated.

It has been suggested with regard to them that they may be [illegible] ifferent stages of, one and the same ty[illegible] This suggestion falls in with the fact that in one of the cases of pyorrhœa alveolaris which I have had under examination there were to be seen many forms transitional between the thicker and shorter form denoted the bacillus fusiformis and the thinner and longer form denoted the spirillum buccæ. It is hardly necessary to point out that the suggestion of a common origin for the two forms a[illegible] nnexion with the suggestion o[illegible] e a trypanosoma stage in the [illegible] spirilla. Two furth[illegible] to. (*a*) The first applies to a case where the pathological affection of the mouth takes the form of a chronic herpetiform eruption on the lips and the development of plaques upon the inner surface of the cheek in the neighbourhood of the angle of the mouth and elsewhere. Here felted masses of the so-called bacillus fusiformis are found in preparations made by puncturing the plaques. This is of interest in connexion with the fact that the development of plaques is a characteristic feature in dourine, a form of trypanosoma invasion which affects in particular the genital system of the horse. (*b*) A condition of extreme anæmia whi[illegible] lood infection is often associated wi[illegible] In the two cases I have had under [illegible] each case examined the blood films [illegible] tive results.

In conclusion, I desire to express my thanks and obligation to Captain S. R. Douglas, I.M.S., for valuable help and suggestion in connexion with the investigation of these cases.

Lower Seymour-street, W.

THE TREATMENT OF CONGENITAL EQUINO-VARUS DURING EARLY INFANCY.

By E. LAMING EVANS, M.A., M.D. Cantab.,
F.R.C.S. Eng.,
SURGEON TO THE ROYAL ORTHOPÆDIC HOSPITAL.

The question of the treatment of congenital equino-varus during early infancy is not only of supreme importance to the patient but also of great interest to the surgeon because of the difficulty in obtaining consistently good results and of the divergence of opinion as to the methods to be adopted. Indeed, few surgical subjects of such antiquity possess so many different principles and multifarious practices at the present day, neither can it be claimed that the literature upon the subject is not full and exhaustive. It is this ambiguity upon the subject that leads to the number of incomplete corrections that present themselves to our hospitals and induces me to record my experience during the year 1903. During that period 53 cases of congenital equino-varus were treated by me. Two cases were so slight that they were treated solely by manipulation. Of the remaining 51 cases, 40 were of the nature of relapsed cases or incomplete corrections, or were primary cases neglected during early infancy. These were all treated as in-patients, some by tenotomy, fasciotomy, syndesmotomy, and manipulation; others by the more severe methods of tarsal osteectomy or subcartilaginous enucleation. The remaining 11 cases presented themselves during early infancy and were treated as out-patients. They represented varying severities of the so-called second degree; in no case could the inversion, adduction, or plantar flexion be temporarily corrected by manipulation, however forcible. The age varied from two weeks to six months, averaging eight weeks. Nine cases were males and two were females. 14 feet were affected, the right foot in nine cases and the left foot in five.

The method of treatment adopted in all these cases was a slight modification of that first introduced by Dr. W. T. Little and afterwards emphasised by Mr. W. Adams. It is usually ascribed to the latter on the continent. It is an amalgamation of the principles of the mechanical method of Scarpa with the practice of subcutaneous tenotomy of Stromeyer. It consists of two stages: (1) the correction of the varus and (2) the correction of the equinus. Stage 1 is commenced as early as possible, in this anticipating the original operation by a few months. It consists of the subcutaneous division of the tendons of the tibiales anticus and posticus and flexor longus digitorum above the ankle-joint with immediate rectification of the varus so far as possible with subsequent manipulation to complete the correction, and in the intervals of manipulation the retention of the foot in the improved position by means of a padded malleable-iron splint. Manipulation at this stage is directed entirely to the correction and over-correction of the varus at the mid-tarsal joint. So long as, at this stage, the tendo Achillis remains taut, all movements in the ankle and astragalo-calcaneal joints are prevented, and we are at a mechanical advantage in overcoming the adduction and inversion at the mid-tarsal joints by being able to manipulate the fore part of the foot upon, as it were, a solid bar of bone extending from that joint to the knee. The method of manipulation cannot be bette [illegible] in the words of Hippocrates [illegible] ub-foot: "In a word, as if [illegible] must bring to their natural [illegible] normally displaced and, co [illegible] g them with your hands and with the bandaging in like manner as to bring them into their natural position, not by force, but gently." The time taken to correct the varus averaged in my series 30 days.

The main advantages of a malleable-iron splint over plaster-of-P. [illegible] carried out at home in [illegible]; (2) if the bandage or [illegible] an be taken off, dried, and reapplied or a second set can be immediately substituted; (3) the mechanical advantage is greater; and (4) the risk of ulceration of the skin is diminished. No ulceration or excoriation occurred in my series.

The second stage is then commenced without delay by subcutaneous division of the tendo Achillis with immediate rectification as far as possible and subsequent manipulation to complete the correction of the equinus, with retention of the foot in the intervals in a padded tin shoe of special design. This shoe has to be worn day and night and is only taken off for manipulation of the foot. It consists of a foot- and leg-piece firmly connected together, the foot-piece being set so as slightly to evert and to dorsi-flex the foot By this shoe the foot is kept in an over-corrected position until the child begins to walk. Manipulation at the ankle is carried out at a great mechanical disadvantage, for the length of the fulcrum measures only from behind the mid-tarsal joint to the centre of the ankle. Care must be taken that an apparent correction of the equinus is not obtained by an over-extension at the mid-tarsal joint. This is liable to occur unless the anterior limit of the fulcrum is persistently borne in mind. The time occupied in correcting the equinus varies more than that of the varus and in my experience is usually longer. It is well at this stage to commence to correct any internal rotation of the leg or thigh by manipulation.

The results of the treatment may be recorded thus: feet with full correction, nine; feet with incomplete correction of the equinus, two; foot with incomplete correction of the equino-varus, one. The deformity in this case is associated with a condition of Mongolian imbecility. Two cases cannot be recorded, as one has left London and the other is in a [illegible] of the internal rotation [illegible] in all these cases.

[illegible] The maximum effect of [illegible] tion of the deformity. Relapse is constantly tending to occur in all and certainly will in some unless means are adopted to prevent that tendency. These means consist of a short daily manipulation, aided in the majority of cases, and in practically all hospital cases, by some form of walking apparatus. Hippocrates clearly recognised and insisted that cure by his method of manipulation was not attained till adult life, for he says, "This, then, is the mode of cure and it requires neither cutting, burning, nor any other complex means, for such cases sooner yield to treatment than one would believe. However, they are to be fairly mastered only by time and not until the body has grown up in the natural shape." The time occupied in the correction is shortened since the days of Hippocrates but not that in the cure.

The treatment of congenital equino-varus may be divided into two main schools: (1) those who treat during early infancy, employing various methods; and (2) those who wait till childhood has well advanced and then correct by one of the various major operative procedures. To turn to the latter first, the arguments used in its favour are the dangers of chloroform during early infancy, the risk of ulceration from pressure of the plaster case, the insufficient support of the latter because it softens with the urine, the long course of [illegible] child suffers pain, and the [illegible] The chloroform argument [illegible] ie risk in the hands of a [illegible] at the age of eight weeks for simple manipulation or tenotomy than it is at the age of six years for an extensive tarsectomy; and, secondly, in ten cases out of 11 in this series no chloroform at all was used. The plaster-of-Paris argument does not apply to this method as it was not used [illegible] ment requires full con[illegible] ing all treatment till, [illegible] performing tarsectomy six years of treatment are avoided, but during those six years the child is crippled and deformed and a lasting impression is liable to be made upon the developing mind. I know of no serious claim for treatment of congenital equino-varus, except after-treatment, by which relapse can be avoided and I hold that no case can be claimed to be cured until the period when all growth has stopped. It is true that cases treated by tarsectomy at this age with subsequent ankylosis relapse less frequently than those treated by methods which retain free mobility of the tarsal joints, but such cases do relapse and it is impossible to say that any one particular case will not relapse; hence it is necessary to bestow care and supervision in all cases treated by tarsectomy and after-treatment in those which show a tendency to relapse. In my experience the most troublesome cases that we have to deal with are those which have relapsed after extensive bone sections and obliteration of many joints and I have grave doubts if the time occupied by the treatment of a series of cases at the age of six years by tarsectomy would be materially less than of a series commenced in early infancy, provided the mothers are stimulated by the surgeon to carry out his simple directions with care, perseverance, and enthusiasm.

In the present series three cases have been under treatment for 12 months and the patients have attended the hospital on the average 16 times, and I anticipate their attendance four times a year until the age of six years, thus bringing the total attendances to 36 in six years. In the case of a tarsectomy we must allow a stay in the hospital of at least 18 days. We can thus see that the figures are not altogether so unfavourable to the early treatment. The pain is slight and is inflicted at a time when the memory is undeveloped and impressions are obliterated at once. Indeed, in their treatment these babies often do not cry at all and if they do the cry is far less vigorous than that caused by the stimulus of an empty stomach. This argument need scarcely be considered further. This school is of recent date and is tending to grow and to cast into oblivion those apparently tedious and protracted means by which the treatment was carried out with steady advancement during the middle third of the last century. It depends upon the perfection of aseptic methods by which the surgeon can adopt more drastic methods with safety to the patient but, as it appears to me, without due regard to the functional activity and æsthetic appearance of the foot.

Far be it from me to minimise the enormous strides that aseptic surgery has enabled us to accomplish in cases of inveterate club-foot of adolescents. Our knowledge of the morbid anatomy has been increased by opportunities for observation during operative proceedings and our treatment has advanced *pari passu* with our knowledge of the morbid anatomy, our results are more certain with our increase in knowledge of the technique of aseptic surgery. All these points have combined to diminish the importance of the advantage, if not the necessity, of treatment during early infancy. I maintain that we should reserve such measures for the all too frequent class of relapsed and neglected cases of adolescence and that we should not be influenced by our success in such cases to slacken our efforts in early infancy.

Turning now to the school that advocates treatment during early infancy the methods are various but usually dogmatic. Thus Erichsen recommends a block-tin splint and manipulation to correct the varus and to convert the compound deformity into simple equinus; then manipulation or tenotomy of the tendo Achillis In a considerable number of cases, he says, the inversion cannot be corrected until the tense structures which maintain it have been divided. Holding that the ligaments of the inner border of the foot play a more important part than the muscles in maintaining the deformity he recommends Parker's syndesmotomy. Accordingly the division of the tendons of the tibial muscles above the ankle has been replaced by the more efficient method of dividing the tense ligaments in the foot itself and by a single operation bringing the foot into the best possible position My experience has so far been that a simple division of the tendo [illegible] flexor longus digitorum, with [illegible] deformity as far as possible [illegible] has sufficed to convert the [illegible] formity in an average of 30 days.

Mr. H. H. Clutton, in Treves's "System of Surgery," advocates manipulation and plaster-of-Paris during the first few months of infant life. If the inversion is in great measure corrected the tendo Achillis and post ligament of the ankle may alone require division. If deformity is uncorrected when the foot has been brought to a right angle or beyond this point he advises Phelps's operation. I think that if the tibial tendons are divided at the commencement of treatment part at any rate of the first few months of infant life are spared manipulation and plaster-of-Paris and if the division of the tendo Achillis is postponed until the varus is completely and not only in great measure corrected Phelps's operation at so tender an age can also be avoided.

The investigations of Parker and Shattock into the morbid anatomy of congenital equino-varus were the first to disturb seriously the ascendancy of Dr. W. J. Little's treatment. Parker advises the division of the tendo Achillis quite early in the treatment of these severe cases, for he says it is impossible properly to gauge the part played by other structures so long as the tendo Achillis remains uncut. The old argument, to leave it quite to the last, that it may serve as a *point d'appui* through which to exert mechanical force on the other structures, is wrong in principle since tenotomy has been introduced. If it prove necessary in any given case it may be taken for granted that the offending structures have not been divided. I have never tried this method in its entirety. I have on a few occasions divided the tendo Achillis before the varus was completely corrected and have found on each occasion the correction of the residual varus troublesome and tedious. I consider that this *point d'appui* is of the greatest advantage in the correction of the varus, for by it we are enabled to mould the cartilage and to diminish the angle of the neck of the astragalus and to straighten out the incurvation of the anterior extremity of the os calcis, both of which points in the morbid anatomy of congenital club-foot were shown by Parker with geometrical accuracy to be offending structures. But I am not aware that he ever divided or advocated division of these cartilages.

And lastly, if we turn for guidance to one of the most modern text-books of the present day we find that Rose and Carless say, "The tibial tendons are usually first divided and the tendo Achillis subsequently, although some surgeons, and especially Mr. Edmund Owen, recommend that the latter should always be first dealt with as this will occasionally suffice alone." No fairer or terser *résumé* of the teaching of the present day could be written than the above, but I must own that if I were confronted on some lone Pacific island with a case of congenital club-foot and given those directions I should be at a loss to know whether to nail my flag to the mast of Mr. Owen's always or to the unrecorded authority for the usual practice.

Bryanston-street, W.

AN EXAMINATION OF APPARATUS PROPOSED FOR THE QUANTITATIVE ADMINISTRATION OF CHLOROFORM.

BY AUGUSTUS D. WALLER, M.D., F.R.S.,

AND

J. H. WELLS, M.R.C.S. ENG., L.R.C.P. LOND.

I.—INTRODUCTORY.

THE subjoined contribution to our knowledge of apparatus proposed for the quantitatively regulated administration of chloroform for anæsthetic purposes formed Chapter III. of a laboratory report of "Experiments and Observations relating to the Question of Chloroform Dosage," based upon experiments by Mr. J. H. Wells and by myself, presented to the special chloroform committee of the British Medical Association in July, 1903. It is important that facts and conclusions obtained by independent investigation relating to the question of safe and unsafe methods of effecting anæsthesia should not remain unpublished. I give, therefore, in its original form Chapter III. of the report (methods and apparatus for regulated administration). The chapter in question forms Section II. of the present paper. My further appreciation of the relative safety of the three forms of apparatus actually recommended in this country is an addition confirmed by further experience. It did not exist in the original report and forms Section III. of the present paper.

II.—QUANTITATIVE ADMINISTRATION.

The practical recommendation of the Scotch school of anæsthetists, "to give plenty of chloroform with plenty of air," translated into precise language, becomes an instruction to administer the vapour *ad libitum* diluted by from 50 to 100 times its volume of air. The large amount of chloroform used and its free admixture with air produce in effect a large volume of mixture and therefore a more nearly uniform supply to the patient's lungs than when small quantities and a closer method with its necessarily frequent alternations of "off" and "on" are resorted to. The drop method is a first approach towards quantitative administration. We have given considerable attention, therefore, to the definition and measurement of a drop of chloroform. The weight of a drop varies, of course, with the orifice of delivery; it is therefore easy to understand the origin of the very divergent weights attributed to a drop of chloroform by English, German, and French authorities. In Germany[1] an average drop of chloroform is stated by Eschbaum to weigh 38 milligrammes (= 7·6 cubic centimetres of vapour). In France[2] a drop of chloroform is stated by Dubois to weigh 66 milligrammes (= 13·2 cubic centimetres of vapour). Our statement is that from an average pipette, and from a stoppered bottle, the drop of chloroform comes out at 20 and 25 milligrammes (four and five cubic centimetres of vapour), and that from a given pipette a drop of chloroform is a very constant amount. Thus a drop of $CHCl_3$, the vapour of which is inhaled with an ordinary inspiration of from 400 to 500 cubic centimetres, supplies a 1 per cent. mixture of chloroform and air. At 16 inspirations per minute 16 drops, or from 0·320 to 0·400 gramme of chloroform at 1 per cent. dilution in air, would be inhaled and absorbed if the inhalation of the vapour were complete and continuous. And on this estimate anæsthesia should be induced in, say, 10 minutes by an absorption of between three and four grammes of chloroform, or between 2 and 2·6 cubic centimetres (*Anglicè* = from 34 to 44 minims, or less than one drachm). We have regarded this small matter as important enough to deserve careful attention and have therefore made series of weighings of chloroform and of water delivery by various pipettes and bottles. We subjoin a series of weights obtained in grammes per 100 drops of liquid.

	Pipette A.	Pipette B.	Pipette C.	Bottle stoppered.	Bottle unstoppered.
100 drops of H_2O ...	5·700	4·606	2·723	13·597	7·193
100 drops of $CHCl_3$ ...	1·849	1·307	1·275	2·285	2·430

Trial of pipettes of various-sized orifices taught us further (1) to adjust the orifice in the blow-pipe so that a pipette shall deliver as nearly as possible drops of chloroform weighing ten or 15 milligrammes—i.e., hundredths of a gramme or of a cubic centimetre; and (2) to use from such pipettes

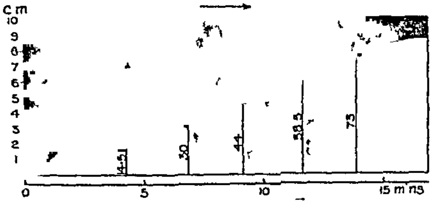
[1] Eschbaum: Deutsche Medicinische Wochenschrift, No. 23, quoted by Dreser in Archiv fur Pharmakologie und Pathologie, Band xxxvii., p. 376.

[2] Dubois: Anesthésie, Paris, 1894, p. 99. The "normal pipette" recently proposed by Yvon (Etude sur le Compte-gouttes Normal, Journal de Pharmacie, 1903) has the following dimensions: Internal diameter, from 0·59 to 0·60 millimetre; external diameter, from 3·00 to 3·05 millimetres; and at the pressure of from two to four centimetres of liquid delivers 20 drops of distilled water to one gramme. The chloroform drop from this pipette weighs 0·0165 gramme; the water drop weighs 0·05 gramme.

the drop of chloroform as a ready and fairly trustworthy measure of a hundredth of a gramme or of a hundredth of a cubic centimetre We subjoin a photographic proof of the degree of accuracy of this measurement of chloroform drops (Fig 1) It exhibits the rise of [illegible] the rise of tension in a closed [illegible] by the introduction of 1, 2 3 a[illegible] a pipette delivering 100 drops [illegible] of the vaporisation [illegible] s mask Chloroform [illegible] heavy as air The next record (Fig 2) exhibits the rise due to introduction of from one to ten drops in a larger closed bottle (1170 cubic centimetres) and incidentally brings out the fact that with increasing density of the little cloud of vapour formed by the successive drops the obstruction to vaporisation increases

FIG 2



Snow's inhaler is set in action by the inspiratory movements of the patient himself Air is drawn into the face piece (and lungs) over chloroform, the surface of which is increased by slips of bibulous paper dipping into the liquid so as to give a mixture of chlorofrom and air that was estimated by Snow to be at 4 or 5 per cent [3] Expiration was provided for by a wide orifice at the face piece inspiratory reflux being there prevented by a valve And in order to provide for the further dilution of the inspired 4 or 5 per cent mixture the expiration orifice of the face piece was arranged to be closed more or less completely by the valve so as to leave a less or more free way for the direct inspiration of atmospheric air thus further diluting the mixture inspired The mixture actually taken into the lungs consisted therefore of two moieties (1) that coming at 4 or 5 per cent over the chloroform surface and (2) that coming directly from the external air At equality of 1 and 2 the mixture inspired was at 2 (or 2·5) per cent with the streams 1 and 2 in the proportion of 1 to 3 or to 4 the mixture was at 1 per cent and so forth Half this value—or 2 per cent —is the normal maximum compatible with effective induction of anæsthesia on the one hand and freedom from unjustifiable danger on the other Snow was working and teaching in 1846 after painstaking observations on himself, and his normal limit was at that time a right and proper statement of opinion But at the present day, by the experience of the last 50 years by the year[illegible] returned in official records and [illegible] he laboratory we are bound to s[illegible] should be induced by the continuous inhalation of chloroform and air between the limits of 1 and 2 per cent The chief defect of Snow's method is however one of which Snow himself was fully aware [4] The ingoing current of $CHCl_3$ depends upon the respiration of the patient and with *diminishing* respiration there is an *increasing* percentage of chloroform inspired The method therefore offers a vicious circle whereby it is certain in conformity with the law of large numbers that a relatively high percentage of accidents must occur in spite of watchfulness by the anæsthetist in spite of the fortunate fact that in given cases 4 or 5 per cent or even more may for a period be administered with impunity Therefore Snow's method and apparatus fell out of use Nevertheless, and chiefly we believe, in consequence of the all but complete abandonment of the attempt to administer quantitatively this potent drug the death rate, as given by the Registrar General's returns, has steadily risen during the last 50 years No doubt the number of cases in which chloroform has been employed has enormously increased and the raw figures of Somerset House are subject to criticism of detail But all discount allowed it remains a reproach to us that cases still occur that can only be referred to ignorance of the power of the drug and of the quantities that are respectively (1) sufficient for anæsthesia and (2) dangerous to life

The apparatus first introduced by Junker in 1860 for the administration of methylene bichloride has been applied to the administration of official $CHCl_3$ and considerably modified for that purpose by various administrators The best known and most widely employed form of apparatus is the model patented and sold by Messrs Krohne and Sesemann It delivers by a face piece freely open to the air, from which the patient inspires definite volumes of chloroform by means of a small accessory pump that drives measured amounts of air through a bottle containing liquid chloroform

In the form of apparatus that we have examined the pump is formed by three elastic balls of a capacity which is intended to be 10 30 and 60 cubic centimetres These amounts are intended to carry into the inspiration ⅙ ½ and 1 minim of chloroform respectively so that on the supposition that the average inspiration of the patient is 400 cubic centimetres the percentage of chloroform in the air of each respiration will be —

10 c.c ball = ⅙ minim $CHCl_3$ = 3 c c. vapour = 0·75% in 400 c.c air
30 c c ball = ½ = 9 c c = 2·25% „ „
60 c c ball = 1 = 17 c c = 4·25%

(This calculation assumes that one cubic centimetre = 17 minims and one minim of $CHCl_3$ = 0·082 gramme yielding approximately 17 cubic centimetres of vapour)

Trials were made under conditions as nearly as possible identical with the conditions of practical application of the apparatus to determine the accuracy of the nominal values Five squeezes of the smallest ball were made delivering approximately 50 cubic centimetres of chloroform-charged air into a flask of 400 cubic centimetre capacity (t = 13·5°C B = 700 mm Hg chloroform flask in water bath at 13·5°) The weight of chloroform delivered to the flask was 0·086 gramme—i e a percentage = 4·0 for five strokes or 0·8 per stroke [5]

A second series of trials was made with the largest ball in a similar way The chloroform found in the flask was 0·064 being a percentage of 3·13 *found* as compared with 4·25 *nominal* and the deficit in practice is even greater than this, as shown by the following series of trials in which the delivery was taken of five successive squeezes —

TABLE I

Temperature of air in laboratory	Weight of $CHCl_3$ in flask	Percentage of vapour in 400 cubic centimetres (nominally 4·25)
15·0° C	0·064	3·13
15·0° C	0·040	1·94
16·5° C	0·046	2·24
17·0° C	0·031	1·53
17·0° C	0·024	1·18

The plan of delivering chloroform vapour into a flask is, we think open to objection our only reason for employing it was that it was desired to use the Harcourt method of combustion and acidimetry as recommended by the chloroform committee for the estimation of chloroform A simpler and more direct method of estimating the amount of chloroform carried over by definite volumes of air pumped through the liquid is to weigh the chloroform vessel before and after each experiment The average loss of weight (calculated from 50 squeezes of each ball) is shown in Table II

Estimations of the CHCl$_3$ delivery by Harcourt's tap and bottle.—In our determinations of the percentage of chloroform vapour delivered by Harcourt's second apparatus[6] the the laboratory, the temperature of tle at the commencement of the and the barometric pressure were noted. In order to avoid obstruction of the inlet of the chloroform bottle the thermometer used for reading off the temperature of the chloroform has only been inserted at the commencement and end of the experiment—i.e., not while air was flowing through the bottle. The methods of determination have been by Harcourt's method and also by the densimetric method. In both series of determinations the air was drawn over the CHCl$_3$ by respiration, at about three-fourths of a litre per minute owing to narrow tubing used. A large flask was inserted between the flask in which the mixture was collected for estimation and the mouth. The size of the flask used for collecting has been in most of the experiments 400 cubic centimetres. In the case of the densimetric method the capacity was 250 cubic centimetres and the inlet and outlet tubes were comparatively small. The percentages obtained by the densimetric method will be seen to be high and we put this down to the fact that the current of air passing over the CHCl$_3$ was slow and the room temperature high.

The accompanying tables give the percentages in each series of experiments. For each case, approximately, ten litres of air were inspired through the titration flask:

Two control bulbs containing chloroform weighed by Dr. N. H. Alcock, the weight of which was unknown to us until after estimation, were taken. The bulbs were placed inside the combustion flask which was then fitted with its cork and platinum wires. The bulb was then broken by shaking the flask. The amount of hydrochloric acid formed at the end of half an hour's combustion was finally estimated by standard ammonia, the same solution being used as for the previous determinations.

Results:—

1. Weight of CHCl$_3$ taken = 0·0873 gramme.
   ,, recovered = 0·08661 ,,
   Recovery = 99·2 per cent.
   Deficit = 0·8 ,,
2. Weight of CHCl$_3$ taken = 0·0795 gramme.
   ,, recovered = 0·07583 ,,
   Recovery = 95·4 per cent.
   Deficit = 4·6 ,,

Each period lasted 3 minutes 40 seconds except in the first three trials (the first lasted 5½ minutes, the second 2 minutes 45 seconds and the third 1 minute 50 seconds) The densimeter percentages in column VI are simply taken out from the numbers of column V If for greater exactitude we take them out by the formula given by Waller and Geets in the *British Medical Journal* of June 20th, 1903, p 1421—*i e*, *log* P = 1 8391 + *log m* − *log* V + *log* T − *log* H *and introduce corrections for temperature and pressure and for the* full capacity which is not 260 cubic centimetres but 254 cubic centimetres—we obtain from the following abbreviated formula (log P = log m + $\bar{2}$ 9923) the percentages shown in column VI A which it was evidently unnecessary to complete The primary purpose of these observations was to calibrate a Harcourt tap and bottle under the conditions of normal respiration Two further points of value are evident from the results 1 That the densimetric method of estimating the percentage of chloroform in mixtures of chloroform and air is exact as well as rapid, the error does not exceed 0 001 gramme 2 That the agreement between the densimeter percentages and the percentages calculated (column IV) from the relation *weight lost volume of air passed* is sufficiently close to permit the percentage delivery of apparatus to be controlled roughly by this means (Densimeter readings require, of course a chemical balance)

FIG 4

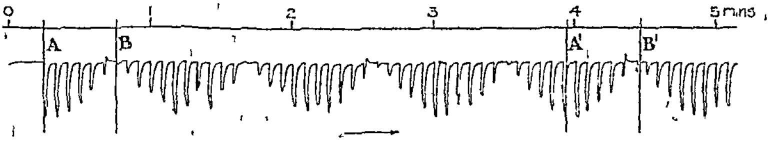

FIG. 5

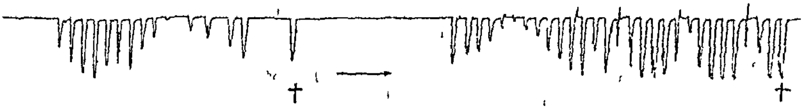

A third and more complete series of determinations was made of the chloroform delivery of a Harcourt's tap and bottle in its improved form[7] and under improved conditions of observation by the densimetric method: A measured volume of air was drawn through the tap and bottle by a suction-pump giving strokes of measured volume every five seconds—i.e., at a rhythm of 12 per minute. The chloroform bottle was weighed at the beginning and the end of the experiment (column III. of Table V.) affording when divided by the corresponding figure of volume from column I. and multiplied by 200 a first percentage datum of chloroform delivery. A 260 cubic centimetre densimeter bulb on the delivery-tube, weighed before and after observation, gave a second percentage datum. The accuracy of this second datum was verified in some cases by twin weighings, in others by a second weighing after washing out by room air and in all cases by the comparison with the first percentage datum. It is, of course, the percentage of the sample 260 cubic centimetres actually present in the bulb that is taken. It had been found that the delivery of the pump (worked up and down by a wheel) was not constant for each stroke but least at the turning-point of the excursion and greatest at the middle of the excursion. Series of strokes were therefore taken, beginning and ending—A at the turning-point of an excursion, B at the middle of an excursion—so as to have a last stroke with air at minimum and air at maximum velocity in each case. The individual densimeter readings exhibit a slight deficit in A and a slight excess in B, as compared with the [illegible] (Fig. 4.) [illegible] of the pump was regular and very fortunately reproduced a phasic or Cheyne-Stokes rhythm. From our recollection of the variation of $CHCl_3$ tenour of the blood found in one of our experiments in correspondence with that rhythm we were led to examine whether a corresponding and opposite variation of percentage would be detectable in inspired air on our artificial animal with Cheyne-Stokes rhythm. In point of fact we found it did with nominal delivery of 1 per cent. The percentage of a sample taken at A was 0·9 and of a sample taken at B 1·2. With irregular and depressed breathing (Fig. 5), imitated by a pump, the percentage was 1·56, with irregular and augmented breathing it was 0·81; in another experiment at nominally 2 per cent. the reading was 1·67 after polypnœa and 2·78 after apnœa. Obviously these were no true mean percentages but merely qualitative indications of a sudden brief increase or decrease in the percentages taken up by the air in the $CHCl_3$ bottle. I have seen an excess of this apparent origin produce the sudden death of a rabbit.

Brodie's tap.—The ordinary method of chloroformisation used in most laboratories is based upon the same principle as that followed by Snow. The animal breathes—or is artificially insufflated—through a bottle with an inlet and outlet tube—or through a two-necked bottle—containing a little chloroform. The method is well known to be dangerous; animals frequently die even when the operator has been watchful; and the risk is greater with spontaneous than with artificial respiration, because in the former case the percentage of chloroform *increases* as respiration *decreases.*[8] To diminish the risk of this method Brodie[9] has adapted a regulating tap to the delivery tube of the chloroform vessel enabling the operator to dilute the mixture of chloroform and air by a further proportion of air as he may think fit. For the same reason—viz., because of the risk attendant upon the use of chloroform in this manner—I prefer to maintain anæsthesia by ether, using chloroform vapour of known percentage for the induction of anæsthesia. Brodie's tap has, however, fully answered the purpose for which it was designed; we are informed by Dr. Brodie himself that since it has been in use he has never had a chloroform accident. The fact is very intelligible; the estimates of percentage made at his request by one of us (Wells) show that the maximum percentage with the tap "full on" does not exceed 3 per cent. The following figures give the results of trials of Brodie's tap with an air current A driven, B drawn, through the chloroform vessel at the room temperature of from 19° to 20°.

TABLE VI.

Tap.	A, by propulsion.	B, by suction
Half on.	0·65 per cent.	1·66 per cent.
Full on.	1·01 ,,	2·87 ,,

The air driven over by means of an artificial respiration pump came out at a lower chloroform percentage than the air drawn through by ordinary respiration; the difference was due to the fact that a larger volume of air passed through the bottle in the former than in the latter case. No gas meter was at the time available for the determination of these volumes.

Dubois's apparatus consists of a pump delivering continuously at any convenient rate between four and 20 litres per minute air charged with chloroform vapour at the nominal percentages of 1·2, 1·6, and 2·0. In a first rough trial lasting for two hours we found that the apparatus delivered a total volume of air of 1260 litres that took up 90 cubic centimetres, 135 grammes, of chloroform—i.e., 27 litres of chloroform vapour. This was a mixture of chloroform and air at a percentage of 2·14 per cent. (The total quantity of chloroform was ascertained by weighing; that of the air delivered was read off on a gas-meter.) Densimetric readings of samples of the mixture taken during the course of the trial were as follows: 2·0, 2·1, 2·1, and 1·9. We then submitted various animals to this mixture, placing them for the purpose under a bell-jar (capacity of 31 litres) through which the above mixture was driven at the rate of from ten to 20 litres per minute. Anæsthesia of a depth sufficient to permit surgical operation was induced in the following times:—

Minimum	4	minutes.
Maximum	8	,,
Average (37 trials on 24 cats)	5½	,,

In conclusion, I venture to repeat three statements made in 1897 and 1898[10]:—

1. Chloroform is not an uncertain agent. The effects it produces are proportional to the mass in which it acts.

2. For ordinary anæsthesia of the human subject the chloroform inspired should be between the limits of *1* and *2* per cent.

3. Death by chloroform is in the great majority of cases death by simple overdose.

And from the observations now reported to add:—

4. In the three forms of apparatus professing to deliver graduated amounts of chloroform the delivery under laboratory conditions is practically what it professes to be. The choice of apparatus is a matter of clinical convenience.

III.—SUMMARY REVIEW.

The clinical convenience of any given method of graduated chloroform anæsthesia is a far graver matter than mere ordinary convenience. From a clinical standpoint the apparatus that is the most convenient is also the most safe and it is not sufficient in a matter where instant and sudden death may be the immediate consequence of an irregularity of administration to be in possession of apparatus capable of delivering graduated amounts of chloroform under laboratory conditions; that method or apparatus is the safest by which under clinical conditions and in spite of the unavoidable irregularities due to the anæsthetist or the anæsthetised greatest uniformity and regularity of chloroform intake shall be maintained.

The dangers of administration by towel or lint are well known and can be minimised by expert administration. "Plenty of chloroform with plenty of air" is a maxim conducive to safe anæsthesia. And by means of densimetric determinations I have shown that the ordinary percentage of mixture of chloroform and air offered to respiration by this rough method lies between the desired limits of *1* and *2* per cent. The great danger of the method is cramming the chloroform fabric over the patient's face, when the percentage may be 10, more or less—i.e., five times the upper limit of safety.

---

[7] I.e., of the instrument patented under the designation of Harcourt's regulating inhaler, sold by Messrs. Griffin and Co.

[8] Worse errors may occur if the operator is careless; in one of our experiments a cat that had been successfully anæsthetised six times was anæsthetised in this way through a tracheal cannula; the animal stopped breathing and was allowed to go on again so as to inspire air that had stagnated in the chloroform bottle so [illegible] accident. The animal died from sudden cardi[illegible] cardiac dyspnœa and could not be recovered [illegible] In another cat, where there was considerable obstruction of respiration by reason of apparatus connected with the trachea to estimate ingoing and outgoing chloroform, a similar "accident" was reproduced with a chloroform percentage = 5·75 (Record of Experiment 23).

[9] Brodie: Proceedings of the Physiological Society, Jan. 18th, 1902.

[10] Brit. Med. Jour., 1897-98.

Of the three apparatus for graduated administration examined above I consider that the order of clinical convenience and safety is (1) the Dubois pump, (2) the Junker apparatus, and (3) the Harcourt inhaler In all three methods the delivery under laboratory conditions is practically what it professes to be but for clinical use each method has merits and demerits of which the general resultant is in my opinion in the order just stated In my experience the principal points in the three cases respectively are as follows

1 *The Dubois pump* —The delivery of a more than sufficient volume of chloroform and air at percentages variable from 1 to 2 per cent is correct in principle and easily accomplished in practice *The induction of anæsthesia is gradual* and regular The depth of anæsthesia is under control There is no immediate danger caused by a brief remission of attention on the part of the anæsthetist and no undue strain of attention is requisite on his part On the other hand the instrument is expensive (£20) and relatively complicated and heavy (weighing 24 pounds) It can be forced or jammed by a clumsy manipulator in which case however the evil effects are limited to the machine and do not increase danger of life The surplus chloroform is inconvenient to anæsthetist and to operator (This inconvenience is however trifling a surplus of 10 litres of 2 per cent mixture escaping into a space of one cubic metre gives a 2 per 10 000 dilution—i e it would take about 420 litres of 2 per cent diffusing throughout an unventilated room 15 feet × 10 feet × 10 feet to give this same dilution of 2 per 10 000) If used on a rickety table the delivery may be irregular this disadvantage can be avoided by the use of a three legged stool

The Junker apparatus (Krohne and Sesemann) —The delivery of a just sufficient proportion of chloroform vapour at the commencement of inspiration is equally a correct principle but practically a very difficult matter to realise The volume of inspiration varies the delivery of a precise volume of vapour varies the precise delivery at the commencement of each inspiration is difficult to secure and the tax upon the attention of the administrator is exceedingly heavy In many instances no regard is paid to the synchronism between inspiration and chloroform delivery sometimes the synchronism is quite impossible to observe The actual strength of chloroformisation must then be considerably in excess of its nominal strength

The Harcourt inhaler (Messrs Griffin and Co) —An intake of chloroform governed by the patient's own respiration is theoretically an unsound principle although it is the first to commend itself for adoption to anyone acquainted with the physical properties of chloroform and with perfect apparatus and a motionless patient it may no doubt be safely employed by an administrator familiar with the physical properties of chloroform The principle cannot however be safely carried out without *close attention to detail on the part of* the administrator and there is in my opinion considerable risk of overdose The mask must fit the face perfectly if air is to be inspired through the chloroform flask With weakening respiration and slower air draft through the chloroform bottle the percentage of chloroform inspired is above the nominal percentage The instruction to avoid splashing is difficult to fulfil unless the bottle is clamped to a fixed pillar and connected to the face piece by a flexible tube as mentioned to be possible A single shake of the bottle momentarily raises the percentage to more than double its nominal value During agitation of the bottle, such as might easily occur in the attempt to keep the mask applied to a restless patient I have seen the percentage as high as five times the nominal value Under these conditions the instrument maker's scale is worse than useless—it is misleading and dangerous The graduation valid under laboratory conditions is illusory under clinical conditions No scale of quantity is preferable to an illusory scale of quantity To keep a watch on the temperature beads is of importance only if other and more important points are not neglected The instrument is very portable (weighing only one and a half pounds) and not expensive (£5 5s)

The recognition of the general principle that chloroform is not an uncertain reagent, and that it produces effects proportional in gravity to the amount of anæsthetic absorbed, *is of capital importance* That principle should not be allowed to depend upon the fortune of any particular apparatus My own opinion was and is at variance from that of the Special Chloroform Committee of the British Medical Association I regard the principle upon which apparatus such as that of Snow Harcourt and others are based with the chloroform intake dependent upon the patient's own respiration as being very liable to accident by overdose Apparatus such as that of Dubois by which an excess of chloroform and air of known percentage is freely supplied by propulsion to an open and loosely fitting face piece is in my opinion more convenient and therefore safer The price and the weight of the Dubois apparatus appear to me to be of secondary importance And even these secondary objections are very easily disposed of An apparatus composed of a three wick lamp delivering from 1 to 3 per cent of chloroform mixture by evaporation answers all the laboratory purposes of the *Dubois and will no doubt like the Dubois prove to be* clinically convenient

Note —I may take the opportunity of correcting an arithmetical slip in Part I of the lecture experiment described in THE LANCET of Nov 28th 1903 p 1481 when it was said that an animal was fully anæsthetised by chloroform absorbed at the rate of 27 milligrammes per minute The total amount of chloroform absorbed was 270 milligrammes of $CHCl_3$ during a period of 7 minutes 40 seconds so that the rate absorbed per minute was 35 instead of 27 milligrammes In Table V there is an apparent error by taking as a percentage datum the relation of column III to column I The error is insignificant and is left uncorrected because it happens to counterbalance a slight temperature error in the opposite direction

Physiological Laboratory University of London

NOTE ON THE CONCENTRATION OF CHLOROFORM VAPOUR IN AIR DRAWN FROM BENEATH A SKINNER'S MASK

BY W LEGGE SYMES M R C S ENG

DEMONSTRATOR OF PHYSIOLOGY IN THE UNIVERSITY OF LONDON

THE subjoined observations were undertaken at the suggestion of Dr A D Waller Their object was to ascertain the concentration of chloroform vapour in air drawn by aspiration from beneath a Skinner's mask in circumstances reproducing in depth and frequency the conditions which obtain when it is drawn from such a mask by respiration of the human subject Aspiration was performed from 10 to 30 times a minute by bellows actuated by a winch and crank and adjusted to aspirate from 350 to 800 cubic centimetres per stroke The aspirated air was sampled in a densimeter *bulb connected to the rest* of the apparatus by indiarubber bags so that it could be stoppered and removed without entrance of atmospheric air [1] The concentration of chloroform in the vapour was determined by weighing the densimeter (*a*) full of air, and (*b*) full of the aspirated vapour and estimating the chloroform from (1) the increase in weight of the bulb due to the chloroform (2) the volume of the bulb and (3) the calculated difference in weight between equal volumes of chloroform vapour and air The second and third factors were so related that at ordinary temperatures and pressures an increase in weight of ten milligrammes indicated 1 per cent of chloroform vapour in the bulb [2] The air stream was maintained through the densimeter in one direction, by means of the valve and returned to the mask by a side tube The mask rested on a folded cloth on which lay the tubes leading to and from the densimeter The amplitude of the aspirations was measured by a spirometer In all observations the temperature of the laboratory was between 15° and 17° C and the height of the barometer was between 755 and 760 millimetres Chloroform was applied to the mask by continuous dropping or by a single douche The concentration of the vapour in the densimeter was substantially constant for an indefinite time during continuous dropping, after a douche it gradually subsided

---

[1] Waller Proceedings of the Physiological Society July 1903 Waller and Collingwood Proceedings of the Physiological Society December 1903

[2] This empirical graduation was checked at intervals by the usual correction for temperature and pressure In no case was the correction of sufficient magnitude to suggest its insertion

TABLE I.—*Showing the Fall in Concentration of the Vapour after Douches on Different Fabrics; Amplitude of Aspirations, 500 cubic centimetres; Frequency, 20 per minute throughout the Series.*

Chloroform used.	Number of aspirations before sampling.	Concentration of vapour.	
		With close fabric on mask (flannel).	With open fabric (domett).

,, ,,	20 ,,	4·25 ,, ,, ,,	3·0 ,,
,, ,,	30 ,,	5 ,, ,, ,,	3·1 ,,

For a given quantity of chloroform used greater frequency led to lower concentration.

TABLE IV.—*Showing the Effect of Varying the Amplitude with Frequencies constant in each Set of Trials.*

Amplitude of aspiration.	Frequency of aspiration.	Chloroform used.	Concentration of vapour.
350 c.c.	20 per min.	55 drops per min.	1·2
700 ,,	20 ,,	69 ,, ,,	1·0
400 ,,	10 ,,	2 c.c. douche.	2·1
800 ,,	10 ,,	2 ,, ,,	2 0
400 ,,	10 ,,	3 ,, ,,	2·5
800 ,,	10 ,,	3 ,, ,,	2·2

For a given quantity of chloroform used, greater amplitude led to lower concentration. The effect of varying amplitude is, however, less marked than that of varying frequency (compare Table III.).

From these experiments it appears that at ordinary room temperatures with moderate and approximately equal quantities of chloroform the Skinner mask yielded vapour of fairly uniform concentration between the desirable limits of 1 and 2 per cent., but reaching as high as 3 or 4 per cent. when the chloroform was copiously applied. The more open of the two fabrics employed gave vapour of higher and, with douches, less uniformly sustained concentration than the closer one. Aspirations of lower frequency and smaller volume led to greater concentration. Comparison of the drop and douche methods showed that a desired concentration is as certainly attained and more uniformly sustained by the former than by the latter.

It is obviously not legitimate to assume that a given quantity of chloroform, whether by drop or douche, would necessarily yield to the human subject vapour of concentration identical with that found above, even if respiration tallied in depth and frequency with the aspiration employed. It is, however, reasonable to conclude that changes in respiration will produce variations in concentration in the same sense as similar variations in physical aspiration, and to emphasise the caution that fall in frequency and depth of respiration may lead to inhalation of dangerously concentrated vapour, even when the amount of chloroform used is apparently not excessive.

University of London.

THE MEDICINAL PEROXIDES HOPOGAN AND EKTOGAN.

BY DR. M. FRENKEL.

WHEN presenting these chemical bodies for the first time to the medical world, in a lecture before the Société de Médecine in Paris about 18 months ago, I felt inwardly convinced of the great therapeutic importance of these preparations, a conviction, however, which was based only upon chemico-physiological facts, such as had been referred to in periodical medical literature.[1]

Hopogan is a peroxide of magnesium and ektogan is a peroxide of zinc Both bodies are very rich in oxygen and their formulæ MgO_2 and ZnO_2, as well as their reaction when tested, show the greatest analogy. Both are definite chemical products exhibiting a constant composition. Both peroxides are producers of oxygen in a very active state. In hopogan, which is destined for internal use, the oxygen is combined with a mild base, magnesia; whilst in ektogan, which is destined for external, surgical, and dermatological application, the oxygen is combined with oxide of zinc. The action of the two peroxides which manifests itself physiologically in their peculiar antiseptic qualities is identical. Hopogan is suitable for use as an internal antiseptic, an anti-fermentative for abnormal stomachic and intestinal fermentations. It differs from other internal antiseptics on account of its non-poisonous, non-astringent, and yet powerful germicidal action. The moment that hydrogen peroxide is formed from the magnesium peroxide and acts on the abnormal fermentation-exciters and fermentation-products it is reduced to water, leaving harmless magnesium salt behind. According to Professor Gilbert, clinical experience shows that no acid is required to liberate the active oxygen contained in hopogan but that the ferments existing in the intestinal juice readily bring about the decomposition of the hopogan and the antiseptic effect connected therewith.

Speaking of clinical results, the trials made by Professor Albert Robin[2] seem to show distinctly that hopogan is a specific anti-fermentative and according to its action the probable origin of diarrhœa may be determined. If diarrhœa is caused through abnormal fermentations hopogan acts with absolute certainty, effecting most rapidly intestinal disinfection and reducing, within 24 hours, for instance, the number of motions from 12 to two of normal condition. On the other hand, Professor Robin says that in cases of diarrhœa of serous or vaso-motorial, or nervous, or tuberculous origin hopogan frequently does not act. This result differs from the one which Professor Gilbert[3] obtained with hopogan. He distinctly says that the peroxide "ne s'est pas montré seulement actif dans les affections gastriques, mais nous avons constaté ses bons effets dans le traitement *de la diarrhée en particulier chez les tuberculeux.*"

[2] Bulletin de la Société de Thérapeutique de Paris, 1904, No. 6, p. 178.

Further observations are needed in order to decide whether hopogan acts as a general anti-diarrhœic or exclusively as an anti-fermentative anti-diarrhœic. Professor Robin, however, describes one case of diarrhœa with phthisis and one with pleurisy successfully treated with hopogan, whilst Professor Gilbert observed rapid success in 11 cases of diarrhœa out of 16 treated with hopogan. The result was negative in one case of tabes dorsalis and in one case of carcinoma of the pancreas in the last stage. In the cases above referred to hopogan was prescribed in the form of keratine capsules in order to obtain the full effect of the active oxygen in the intestines. But with the keratine capsules Professor Robin also combined the treatment with hopogan powder. The dose may be increased from one to three grammes per day.

Professor Gilbert has made numerous trials with hopogan powder and tablets in cases of affections of the stomach produced by abnormal fermentations and in 20 cases out of 22 he has obtained very favourable results. The following conditions were treated: constantly furred tongue, bad taste in the mouth, odourless as well as fetid belching, eructations, sickness, vomiting, and flatulence in the epigastrium accompanied by oppression of the heart after meals. Improvement took place soon after the first or second day, but in order to obtain lasting results the treatment had to be continued for two or three days after disappearance of the last symptoms of illness. During the trials the food of the patients was not modified. Against pains in cases of gastritis alcoholica the preparation was effective in three out of eight. In cases of tuberculous or neoplastic anorexia the result was always negative. Professor Gilbert concludes that it is absolutely due to the oxygen *in statu nascendi* that hopogan has such good effect.

With regard to the action of ektogan Dr. Chaput expresses himself just as categorically. In the treatment of wounds he reported to the Paris Surgical Society some remarkable results. The principle of antisepsis by means of active oxygen is here effectively carried out. The manner of applying the preparation may be in the form of ektogan powder, ointment, or gauze. I will not dwell here upon the details of the copious report and must refer the reader to the original.[4] Suffice it to say that Dr. Chaput concludes his remarks as follows: "Ektogan (peroxide of zinc) is an excellent remedy for the treatment of surgical wounds. It is neither toxic nor caustic; it can be sterilised by heat. When in touch with wounds it develops oxygen continuously. In form of powder, gauze, or ointment it gives excellent results in treatment of aseptic or infected wounds, torpid wounds, eczema, and dermatitis. For uterine and vaginal bandages, ektogan is an advantageous substitute for aseptic and iodoform gauze." It is odourless.

It is satisfactory to find that the good effect of remedies as anticipated by their chemico-physiological behaviour is realised in practical application.

Honfleur, France.

ON THE FREQUENCY OF ASEPTIC NECROBIOSIS OR RED DEGENERATION OF FIBROMYOMATA OF THE UTERUS.

WITH A REPORT OF TWO CASES.

BY FRANK E. TAYLOR, M.A., M.Sc., M.B. VICT., F.R.C.S. ENG.,
PATHOLOGIST, CHELSEA HOSPITAL FOR WOMEN, LONDON.

THE ordinary hard fibromyoma of the uterus presents to the naked eye on cross section a white, glistening, satin-like, whorled appearance which along with its distinct and well-marked encapsulation and its contrast with the surrounding pale pink myometrium is striking and characteristic. Equally striking and characteristic is the appearance presented on cross section of a uterine fibromyoma which is undergoing aseptic necrobiosis or red degeneration. The tumour is usually single, with a well-marked capsule, is softish in consistency, distinctly red, mahogany or liver-coloured, fleshy looking, and loose textured, having been compared to raw beef steak. It will thus be evident that attention is immediately attracted to this condition on making a section of such a tumour, for there is nothing in its external appearance before section to indicate its nature. Hence it is remarkable how little attention has been paid to the latter condition, for in the majority of the gynæcological text-books there is not even the slightest hint that this condition does occur.

The subject has, however, been so recently and so fully described by Dr. J. S. Fairbairn, both from a pathological and from a clinical standpoint, in a paper entitled "A Contribution to the Study of one of the Varieties of Necrotic Change, the [illegible]," in the [illegible] August, [illegible] scription and it is therefore unnecessary again to describe the condition. I would rather limit my few remarks, therefore, to the frequency with which it is found.

The only published statistics that I can find in this connexion are those contained in Dr. Fairbairn's paper, which is chiefly based on material obtained in the pathological department of the Chelsea Hospital for Women. During Dr. Fairbairn's tenure of the office of pathologist 105 specimens of uterine fibromyomata were examined in the pathological laboratory and of these ten, or 9·5 per cent., were affected in this way. During the last two years the pathological department of this hospital has been under my charge and 124 specimens of fibromyoma of the uterus have been examined and only two, or 1·6 per cent., were found showing this condition. These figures, along with those from the gynæcological wards of St. Thomas's Hospital, quoted by Dr. Fairbairn may be tabulated thus:—

—	Number of fibromyomata examined	Number of fibromyomata showing necrobiotic changes.	Percentage affected.
St Thomas's Hospital, 1897–1901 ..	88	7	8 0
Chelsea Hospital for Women, Series I.	105	10	9 5
Chelsea Hospital for Women, Series II.	124	2	1 6
Total . .	317	19	6 0

Thus we have a total of over 300 specimens of fibromyomata of the uterus examined which is, I think, a sufficiently large number to give an approximately correct estimate of the frequency with which these tumours undergo necrobiotic changes, and this works out to very nearly 6 per cent.

The two cases showing this condition in the second series from the Chelsea Hospital for Women (for permission to record which I am indebted to the kindness of Dr. W. H. Fenton and Dr. W. F. Victor Bonney) are as follows.

CASE 1.—A married woman, aged 44 years, was admitted into the Chelsea Hospital for Women on Jan. 8th, 1904, under the care of Dr. Fenton, complaining of menorrhagia, metrorrhagia, burning sensations in the lower abdomen, and pain in the back on sitting. Menstruation commenced at the age of 18 years and was quite regular until marriage at the age of 24 years. The performance of this function has always been attended with much pain. The patient had been married 20 years and had had no children but four miscarriages. Ever since marriage menstruation had been very irregular, generally occurring every two or three weeks and scarcely ever going the full month. The loss had always been free and accompanied by clots and much pain. The condition had been much worse for the last 12 months, the flow gradually becoming more profuse until at last it became continuous. For two months before admission, however, there was complete amenorrhœa. For the last two years the patient had noticed a sensation of pressure in the sacrum on sitting and had had paroxysmal attacks of labour-like pains and burning sensations in the lower abdomen. For the last few months there had also been a thin white vaginal discharge. Micturition had been normal and the bowels ha [illegible] oughout. On palpation of the abdomen [illegible] was discovered but vaginal examination re [illegible] of a tumour lying in the pouch of Douglas. The tumour was of the size of the closed fist, was hard, not tender, more or less fixed, and lay in close relationship to the uterus. It gave to the examining finger the sensation given by a fibromyoma. Immediately in front of it was the cervix, which was displaced forwards close to the pubic symphysis.

---

[3] Comptes Rendus de la Société de Biologie de Paris, 1904, No. 11, p. 486.
[4] Bulletin de la Société de Chirurgie de Paris, 1904, No. 15, p. 437.

Dr. Fenton opened the abdomen on Jan. 15th and explored the pelvis. A large fibroid uterus was found. The tumour was discovered to be growing chiefly from the posterior wall of the uterus and to be burrowing its way down towards the cervix. The uterus with its contained fibroid was removed by supravaginal hysterectomy. Both uterine appendages were removed along with the uterus. The abdominal wound was sewn up in three layers. Recovery was rapid and uneventful except for a slight rise of temperature on the second, third, and fourth days after operation, the highest point reached being 100·4° F. The patient left the hospital on Feb. 3rd, the twentieth day after operation.

An examination of the specimen removed at operation showed an enlarged uterus with both appendages attached. On incising the uterus its posterior wall contained a single interstitial fibromyoma of the size of a cricket ball which was growing down behind the cervix. It presented the red, liver-coloured, loose-textured appearance characteristic of red degeneration. Both uterine appendages appeared to be perfectly normal. Microscopically the sections were found to take on the stain in an irregular and patchy manner, so that portions of the section showed interlacing bundles of fibrous and muscular tissue, in which, as in undegenerated fibromyomata, the nuclei were deeply stained and the muscle bundles clearly differentiated. In adjacent parts the nuclei were more faintly stained, forming "nuclear ghosts," whilst in other places there was an almost entire disappearance of the nuclei. In these places the muscle bundles had also failed to take the stain well and appeared granular and transversely fragmented, having also a somewhat hyaline or swollen appearance, so that the outlines of the individual muscle fibres can only be recognised with difficulty.

CASE 2.—The patient, aged 40 years, was admitted into the Chelsea Hospital for Women under the care of Dr. Bonney on Nov. 2nd, 1903, complaining of swelling of the abdomen. She had been married four years and was sterile. The catamenia had always been regular, lasting four days, and had been very profuse, necessitating the use of 18 diapers. There were no clots until the last period and there had never been any pain. The first symptom to be noticed was swelling in the left iliac region. This was two years before. The abdominal enlargement gradually increased until September, 1903; since then when "she caught a very severe cold" it had become much larger. There had been an absence of pain throughout. There had been no vaginal discharge and micturition and the bowels had been normal. On abdominal examination a large tumour-mass of irregular outline was found to occupy the lower abdomen and to extend slightly above the level of the umbilicus. It was of very dense consistence and slightly moveable. No souffle could be detected over it. On vaginal examination the cervix was almost obliterated from the universal distension which the uterus had undergone from its occupation by the tumour. It was freely moveable.

On Nov. 10th Dr. Bonney performed abdominal hysterectomy, removing the right, but leaving the left, ovary. Recovery was rapid and uneventful, the highest temperature after operation being 99·6° F., and the patient was discharged from hospital on Nov. 27th, 17 days after operation.

In this case also the tumour was a single interstitial fibromyoma rather larger than the closed fist. It was well encapsuled and of the typical homogeneous mahogany-red colour, having also the faint fishy odour, due probably to the presence of trimethylamine. Microscopically there were the uneven and patchy staining of the sections, the appearance in places of "nuclear ghosts" and the almost entire disappearance of nuclei in other places, and the muscle bundles displaying the granular and transversely fragmented or swollen hyaline appearance, with difficulty of recognition of the outlines of the unstriped muscular fibres so characteristic of this condition.

ADENOMYOMA OF THE UTERUS.

By S. J. MURDOCH CAMERON, M.B. GLASG.,
LATE SENIOR RESIDENT MEDICAL OFFICER, MATERNITY HOSPITAL, GLASGOW;

AND

ARCHIBALD LEITCH, M.B. GLASG.,
SENIOR HOUSE SURGEON, CANCER HOSPITAL, LONDON.

ADENOMYOMA of the uterus has escaped proper recognition in this country. With the exception of a paper recently published by Cameron and Taylor[1] we can find no detailed account in British medical literature; since then a few specimens have been shown at the medical societies. We have had the opportunity of investigating several others, some of which are herein referred to, in a comparatively short period of time, a circumstance which leads us to believe that these tumours are not very uncommon and that a routine microscopic examination of uteri, the seat of so-called fibroids, would bring to light many more cases of this interesting condition.

As the name implies, these tumours are new growths composed of muscular and gland elements, the latter typically being imbedded in a richly cellular connective tissue. Situated anteriorly, posteriorly, or laterally in the uterus, subserous, interstitial, or submucous, they have in almost all respects the general macroscopic characteristics of a fibromyoma, with which, indeed, they are sometimes associated, as two of our cases show. There are perhaps only two points which may lead to a diagnosis—the absence of a definite capsule and the absence of whorls so characteristic of fibromyomata. Their commonest situation is dorsally near one or other of the tubal angles. They vary in consistence and have been classified as hard, cystic, soft, and telangiectatic.

The clinical characters are those of fibromyomata, from which we do not think they can be distinguished by examination. Severe dysmenorrhœa and excessive hæmorrhage are, as a rule, marked features and considerably affect the patient's general health. Sterility is by no means an invariable accompaniment and not one of the cases we have seen has been pathologically so, though, according to Freund, the majority are barren. They may have a frail childhood, a laggard puberty, an arrestment of the growth of the sexual organs, and they usually suffer from anæmia. When the tumour occurs in its commonest situation Funke proposes the following as a means of clinical diagnosis: (1) localisation of the tumour at one or other of the tubal openings in the uterus; (2) the diffusely infiltrated consistence of the growth; (3) painfulness on palpation; (4) the severity of the symptoms produced by such a small lesion; (5) the absolutely normal condition of the tube itself; and (6) the improbability of a circumscript infiltration of a part of the uterus amidst healthy surroundings being due to inflammatory processes.

We have little doubt that adenomyomata imperil the life of the patient much more than ordinary fibromyomata. Their association with adenocarcinoma has been noted by several observers,[2] and even in the most regularly formed adenomyomata it is doubtful if one can reckon the possible powers of infiltration. Hysterectomy is therefore the only treatment and when removed successfully the result to the patient is excellent. Castration is useless and in no way influences the tumour growth.[3]

Microscopically they are composed of gland tubules imbedded in muscular tissue. The gland cells may abut directly on the muscular fibres but in the great majority of cases there is more or less intervening cellular tissue. The relative proportion of the constituents determines the consistence of the tumour, hard adenomyoma having a preponderance of muscular tissue, soft adenomyoma being composed mostly of adenomatous and lymphadenoid tissue. The tubules may be much distended and cystic spaces so formed are obvious to the naked eye—cystic adenomyomata. The tubules are composed of a single layer of columnar, sometimes ciliated (see Fig. 1), epithelial cells, each of which contains a single round oval or even rod shaped nucleus of good staining property The basement membrane is intact Where the tubules are dilated the epithelium becomes cubical, flattened or is quite lost The spaces contain clear fluid in which may be found a few red blood corpuscles or the remnants of epithelial cells nuclei with some attached protoplasm Surrounding the tubules is a richly cellular lymphadenoid stroma composed of round spindle shaped or many branched cells with round nuclei—a tissue identical with the extraglandular stroma of the normal corporeal endometrium A varying number of tubules are imbedded in and separated from each other and the surrounding muscle by this cellular mass, there is usually a central acinus larger than the others and their relative position shown in Fig 2 like foot tracks on soil has been described

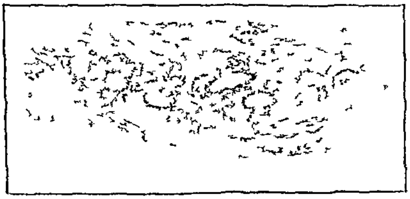
FIG 2



Camera lucida drawing of a glandular islet surrounded by muscle

as the tumours in

which this arrange

ment i the section

separated by muscular strands In the same section one may find both conditions—the association of several acini in a cellular islet and the direct juxtaposition of gland and muscle without intervening stroma In tumours belonging to the latter type there is a tendency to intraglandular inversion of the epithelium a fold of epithelium still keeping its basement membrane intact grows into the lumen and is approached by a similar plication from the opposite side the epithelial summits meet and losing their epithelium coalesce and the basement membranes offering no resistance the two processes of ingrowing fibrous tissue become continuous At other parts in place of complete glandular subdivision such as this there is a simple intracystic growth a more or less dichotomous branching of the inverting epithelium The infiltrating character of the growth combined with this tendency seems to us to raise it from the category of typically simple tumours As in fibromyomata the relative proportions of muscular and fibrous tissue vary Well formed blood vessels frequently with hypertrophied coats, are found in the muscular tissue as well as more delicate vessels in the cellular islets, in the very soft telangiectatic variety of adenomyomata the blood vessels are extremely numerous and there may be dilated blood spaces Frequently perhaps in the great majority of cases a definite connexion between the gland containing cellular islets and the endometrium is to be found the utricular glands and interglandular stroma dipping down into the myometrium, evidently continuous with the glandular constituents of the tumour A microscopic section would of course show several of these endometrial inclusions as islets completely surrounded by muscle This encroachment of endometrium on myometrium is not uncommon in hypertrophic endometritis and sections of the latter might show an occasional inclusion but we do not think the presence of such merely directly under the endometrium in the absence of any definite tumour formation would justify the name of adenomyoma

The cases here related will illustrate the foregoing sketch

CASE 1 —We are very grateful to Mr J Bland Sutton for this case The patient was 49 years of age and had sought advice for severe hæmorrhages occurring over a period of three years She was a multipara and her last pregnancy occurred six years previously The diagnosis of fibromyoma of the uterus was made and consequently supravaginal hysterectomy was performed The uterus was five inches in length and before section the appearance denoted the occurrence of an intramural fibroid However on section no capsule to the growth could be observed and the whole wall could be differentiated into three layers 1 A layer of ragged endometrium 2 A mass of striated tissue the fibres of which intersected each other in all directions The absence of whorling was readily noticed 3 A layer of ordinary uterine muscle about one third of an inch in thickness This condition existed in the whole uterine body On microscopic examination the growth was found to be characteristic of adenomyoma Gland spaces occurred throughout the sections an abundant stroma resembling in every detail the tissue met with immediately under the lining epithelium of the uterus separated these tubules from the surrounding fibro muscular structure The epithelium of the tubules was columnar in shape and these were placed on a basement membrane which at every part was quite intact No cilia could be detected in any of the spaces but the epithelium otherwise resembled that of normal endometrium At certain parts the endometrium could be seen dipping into the uterine wall so that here and there the rich lymphadenoid tissue around the acini communicated directly with that in the endometrium At other parts the muscular fibres of the uterus could be seen encroaching on these peninsula like ingrowths and eventually on the muscular fibres becoming approximated an islet consisting of uterine endometrium lay inclosed in muscular tissue

CASE 2 —For the kind permission to use this case we are indebted to Mr F B Jessett The patient was aged 33 years She had been married 11 years She had had two children and two miscarriages Her previous health had been good and the menstrual history was unimportant Three years previously when five months pregnant she fell

from a train she was not

consequently aborted Sh

months with pelvic pain

since menstruation had bee

or four severe floodings

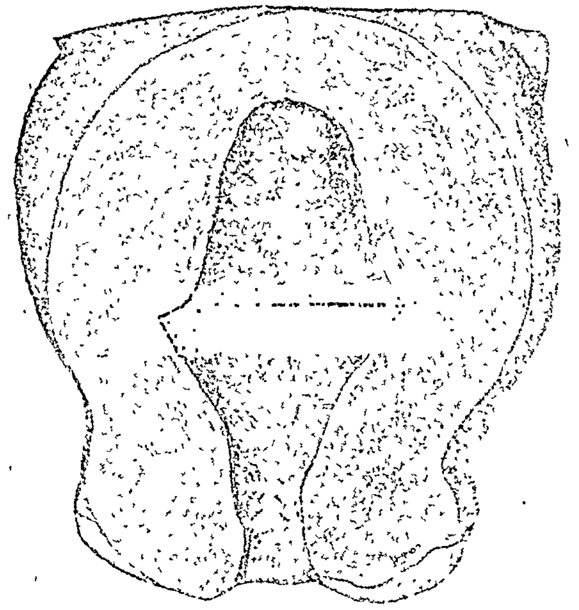
nine or ten days without some hæmorrhage There were no bladder or rectal symptoms She was not markedly anæmic The uterus which was removed by vaginal hysterectomy was of about the size of a three months pregnancy The cavity was three and a half inches long by one and a half inches broad towards the middle The walls were thickened on all sides especially ventrally where the distance from serosa to mucosa was two inches There was no encapsulation of this part Three strata could be determined—a layer under the endometrium a quarter of an inch thick a roughly reticulated stratum in the middle and an external regular muscular layer half an inch thick Two small polypi of the respective sizes of a filbert and a pea were found projecting into the cavity near the fundus (Fig 3) Microscopically the tumour consisted of muscular tissue the

---

4 Ibid

strands running in all directions, and a relatively smaller proportion of well-formed gland tubules. There was practically no lymphadenoid stroma around the epithelium and, save for the intervention of a few connective tissue fibres at parts, it rested directly on the muscle. The epithelial cells were cylindrical and their nuclei lay close to the basement membrane. There was a tendency to intraglandular plication so that the contour towards the lumen was a wavy circular line. The fibrous tissue and muscular stroma followed these indentations. There was no round cell infiltration anywhere observable. The muscular stratum under the serosa was free from gland canals.

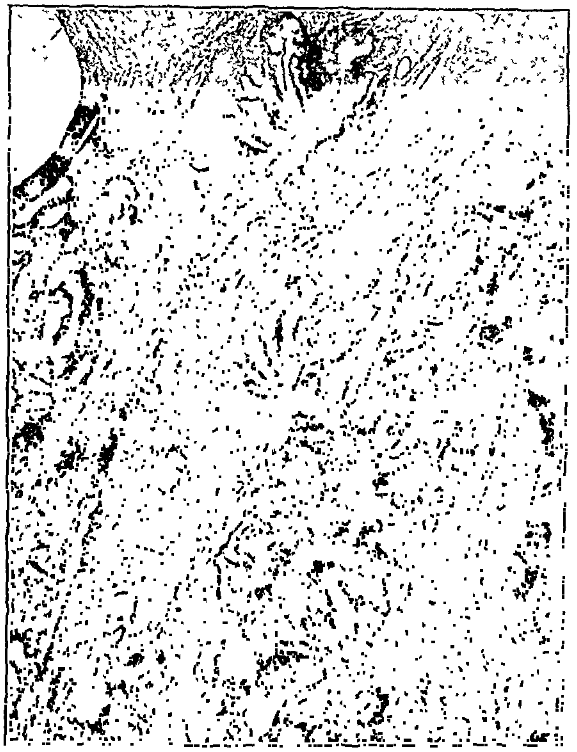
FIG. 3.



Adenoma uteri diffusum benignum. (Mr. F. B. Jessett's case.)

CASE 3.—For permission to make use of this specimen we are indebted to Professor Murdoch Cameron and Dr. Alexander McLennan. It was removed from the anterior lip of the cervix by Professor Murdoch Cameron who described the appearance of the tumour at the time of its removal as resembling very closely a multilocular cyst. The patient had all the symptoms which are found in association with intra-uterine polypi. The tumour attained the dimensions of a cocoanut and on examination it was exceedingly like a multilocular ovarian cyst, the superficial parts of the tumour being raised into irregular masses by cystic cavities in the growth varying from the size of an orange to very minute glandular spaces. The covering of these cysts was very thin, while the portions intervening were of firm consistency. On section it was found to be composed for the most part of cavities which contained mucus and here and there free communication existed between neighbouring spaces. The fluid on boiling did not coagulate. These spaces were separated by tissue which to the naked eye seemed to be fibromyomatous and in a somewhat œdematous condition and on microscopic examination these portions were found to be in a degenerated condition, the stain being faintly taken up. The cystic spaces were found to be singularly beautiful in the perfection of their structure, resembling very closely the microscopic characters of an ovarian cystadenoma. The glandular spaces were lined by a perfectly uniform row of columnar epithelium which had an intact basement membrane resting directly on the surrounding fibro-muscular tissue. At the base of each cell there was a single nucleus which took up the stain readily. In many of the spaces well-marked papillomatous projections existed which extended in the more marked papillæ almost to the opposite wall of the cavity, a strand of fibro-muscular tissue following the epithelium into the lumen. Such was the degree of projection at certain portions that the apices of adjacent papillæ met and the epithelium at the point of contact disappeared, so that a space was thus formed in a secondary manner from these two papillæ. This space resembled the original glandular formations in every respect. The formation of such an adenomatous structure is exac[illegible] [illegible] it which is found in the tubes in certain [illegible] In other spaces the projections were extremely small, so that the lining epithelium had simply a number of small undulations next the lumen. In some of the larger cavities where cystic distension had been very great the epithelium had completely disappeared and here and there a few flattened cells represented what was once a well-defined cylindrical epithelium. In such spaces the fibro-muscular tissue formed for the greater part the limits of the cavity. A cervical adenomyomatous polyp of such dimensions as the above must be of very rare occurrence (Fig. 4).

FIG. 4.



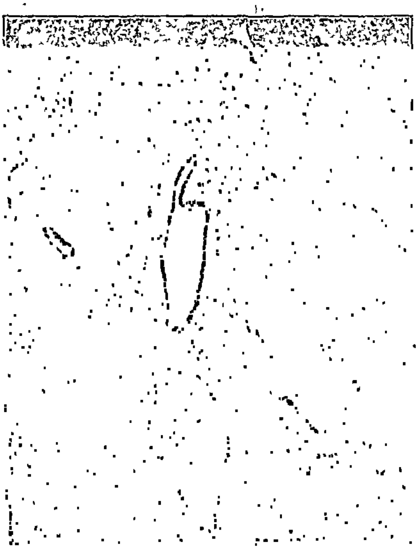
Section of a cervical adenomyomatous polypus showing subdivision of gland spaces.

CASE 4.—The patient was aged 39 years, married, and the mother of four children. She had been delicate in childhood. Menstruation had started at 14 years of age. She had always been regular save for the intermissions of pregnancy but the periods had always been of long duration, nine days on the average and fairly copious. She was blonde and pale. Lately, the onset of the period had been accompanied by severe pain referred to the lower part of the abdomen and there had been severe hæmorrhage at and between the periods. The uterus was not felt to be enlarged bimanually but painful under the examining hand on the fundus. The ovaries appeared to be normal and were not painful; the tubes were normal. Bimanually, with one finger in the rectum, the fundus uteri towards the left was excessively tender. There was no bladder trouble. The patient was of a constipated habit and required to keep the bowels loose by medicine to obviate pain on defecation. Laparotomy was performed and the uterus was removed. The uterus was normal in size but on the fundal angle just behind the uterine junction of the left tube there was a slightly raised flat whitish circular patch under the intact peritoneum. In cutting into it it was hard to the knife, almost regularly hemispherical, and approached the cavity on its inner convexity. It was of about the size of a half walnut. It was circumscribed by normal uterine tissue. It appeared to be a fibromyoma and its true nature was only discovered after microscopic section; consequently we were not so careful as we might have been in the rough section and though serial sections were afterwards made in no case unfortunately was one obtained without muscular strands intervening between the endometrium and the tumour proper. Microscopically the tumour was composed of bundles of muscular tissue running in various directions, inclosing and separating from each other, many well-formed circular, oval, or irregularly shaped gland acini. In the smaller tubules the epithelium was columnar, in the larger cubical, and each cell was occupied by a round or oval nucleus. The epithelium, too, at various parts of the tumour was ciliated (Fig. 1). At some parts there was a fair amount of lymphadenoid stroma between the acini and the muscle, at others the epithelium abutted directly on the muscle. Seldom were two sections of gland tubules found in the same islet. The blood-vessels were fairly numerous and had hypertrophied walls. Gland cells existed quite close to the serous coat. The endometrium was apparently normal.

Several theories of origin have been put forward. The inevitable microbic origin has received the support of some French observers mainly on the slender ground of occasional leucocytosis. Cullen has described the presence of giant cells but no tubercle bacilli have been found. Eschoff considers that the peritoneum covering a myoma may dip into it, be cut off, and by proliferation form the adenomatous constituent. [illegible] probability of metaplasia of [illegible] It has received no independent support. Most continental and American observers refer the tumour to mucosal origin. Von Recklinghausen[5] was strongly of opinion that uterine adenomyomata almost exclusively owed their origin to persistent remains of the Wolffian duct and of his 33 cases referred only one to a mucosal origin. In early fœtal life the Müllerian and mesonephric ducts lie in close proximity from the kidney to the urogenital sinus. Below, the Müllerian ducts coalesce to form the uterus and vagina; above, diverging, they form the Fallopian tubes; and it is at the uterine junction of the latter with the uterus that the Wolffian ducts lying dorsally come to have an intimate relation with the uterus. Persisting as rudimentary canals in ruminants and swine—Gärtner's canal—the Wolffian duct in the human adult has as a rule entirely disappeared except the terminal portion inclosed in the substance of the neck of the uterus and still distinguishable but only by means of cross sections as an extremely narrow tubule (Beigel, H. Dohrn). Rest cells derived from the Wolffian ducts have been found under the serosa, especially near the tubal angles, by Klein and others. Adenomyomata have been found over the course of the Wolffian ducts—in the Fallopian tubes, broad ligaments, and vagina. The glandular elements arising from the Wolffian remains in the uterus would stimulate a hyperplasia of the muscle and thus form the other element of the tumour. This explanation of von Recklinghausen would seem to account for subserous adenomyomata towards the uterine cornua posteriorly but it breaks down with regard to submucous adenomyomata, dorsal or ventral, or more or less generalised growths. The evident connexion between the endometrium and the glandular islets of the tumour and the identity of their component parts seen in so many cases make the mucosal origin of these practically certain, and even [illegible] ble [illegible] uld [illegible] it is unlikely that perfectly formed tubules of such a highly specialised structure as ciliated epithelium could originate from embryonic remains, which have presumably long lain dormant, and the fact that cilia are present in a tumour which has intact peritoneum over it seems to point strongly to a connexion with the uterine cavity. The failure to establish an endometrial connexion in a microscopic preparation may be due to the fortune of the particular section and the connexion might be revealed by serial sections, but if even then it is not obtained a mucosal origin is not negatived, for by the growth of the muscular constituent the tumour might be insulated. The presence or absence of a lymphadenoid setting of the acini does not point either way, for in Case 4, where no endometrial connexion was determined by the sections, there was at parts more or less lymphadenoid stroma, and in Case 3—a polypoid growth—and in Case 2, where there was presumptive evidence of endometrial origin, there was practically none.

The association of adenocarcinoma with adenomyoma may be more than accidental. Beyea[6] considers that carcinoma of the uterine body may arise from adenomyoma. We are deeply indebted to Dr. Louise McIlroy of Glasgow for providing us with a section showing at one part typical adenocarcinoma with small round-cell infiltration, intraglandular inverting and extraglandular everting of closely packed distorted epithelial cells several layers thick and poor in nuclear staining, their basement membrane lost, and the interglandular stroma reduced to a minimum, and at another part

FIG. 5.



Section of a tumour showing typical adenomyomatous formation.

perfectly formed gland tubules composed of a single row of columnar epithelial cells and the [illegible] the basement membrane intact, the [illegible] of lymphadenoid tissue and the enveloping muscle—typical adenomyoma. Figs. 5 and 6 are reproduced from microphotographs from different parts of the same section. Fig. 6 seems to show the transition from adenomyoma to adenocarcinoma through the intermediary stage of malignant adenoma, the gland canals at that part being lined with a single row of cylindrical epithelium. We have searched several hospital and private collections of uterine tumours without coming across this condition.

To sum up, we would suggest the following as the stages of these tumour formations : first, an ingrowth of the structures of the endometrium into the muscular wall, as is seen in hypertrophic endometritis—the stage of "glandular inclusion"; second, a hyperplasia of the inclusions and a progressive infiltration stimulating a hyperplasia of the muscle—the stage of "adenomyoma benignum"; third, a loss of relations between glandular and muscular elements, the growth of the former outstripping that of the latter, inversion and eversion of the epithelium with a consequent displacement of the interglandular stroma and an encroachment on the muscle, the irritation of the growth causing the round-cell infiltration—the stage of "malignant adenoma"; and fourth, the stage of adenocarcinoma, the loss of relations between one epithelial cell and another, the riotous proliferation and heaping up of immature epithelial cells breaking through the restraining basement membrane, invading and destroying the adjacent muscle.

We have received much help from various friends in the way of specimens of uterine tumours and microscopic slides. We beg to thank Dr. Harold R. D. Spitta of St. George's Hospital for the excellent microphotographs which he has taken for us.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Prooemium.

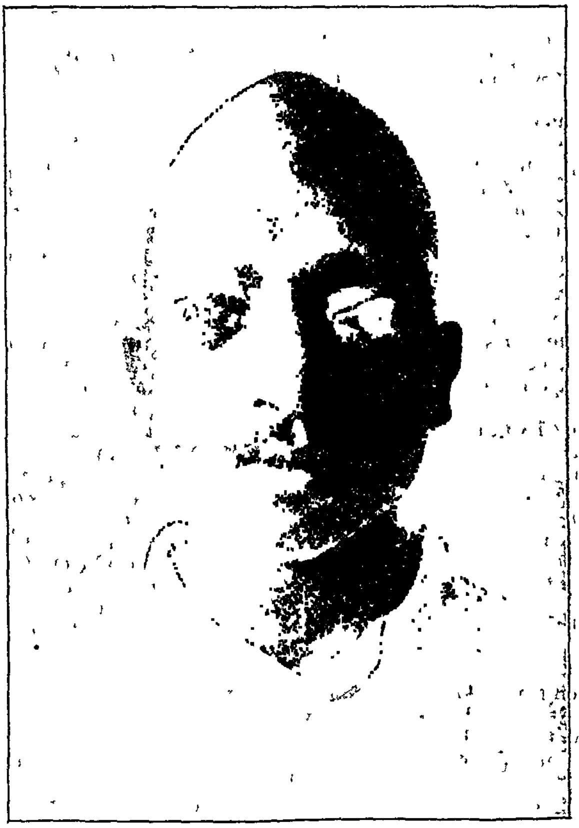
SIR JAMSETJEE JEEJHEBHOY HOSPITAL, BOMBAY.

A CASE OF OCULAR DEFECTS ASSOCIATED WITH CONGENITAL DEFORMITY OF THE CRANIUM (OXYCEPHALY).

(Under the care of Captain E. F. GORDON TUCKER, I.M.S.)

THE patient was admitted into the wards of Captain Tucker in the Sir Jamsetjee Jeejhebhoy Hospital early in September, 1903, for an attack of malarial fever which rapidly responded to treatment. The curious condition of the eyes was at once observed and examination of the cranium showed that the occipital region was very deficient and that the posterior part of the skull was almost on the same plane as the back of the neck. After his head had been shaved the "steeple-shaped" character of the cranial vault was evident. He was a Mahratta and stated that his age was about 20 years and that his eyes had always been prominent. His father was alive and in good health and had no peculiarity of the eyes or the face. His mother died about five years previously, apparently from phthisis ; there were three sisters who died young and there was one brother living who had not ocular defect or peculiarity The patient's work was to look after cattle. He answered questions intelligently; he gave no history of headaches and had always had good health. Vision for distant objects was good. He was of normal height, build, and development. The cranium showed a projection in the form of a ridge from the centre of the vertical portion of the frontal bone to the central point of the vault, which was situated one and a half inches in front of a line drawn perpendicularly upwards from the external auditory meatus. The marked bulging in the temporal regions present in the case of congenital proptosis associated with a curious formation of the cranium in a boy, aged seven years, who showed evidence of some mental deficiency, described by Mr. H. Work Dodd and Mr. W. H. McMullen in THE LANCET of June 13th, 1903, p. 1665, was not evident in this case. The shape of the face was natural. The nose was well-formed. The palate was very high and arched and met at the uppermost part in a deep sulcus. The teeth were very good and not at all crowded together. The neck was of normal shape and there was no enlargement of the thyroid gland. Coördination of muscular movement was quite natural. The measurements of the head and face were as follows: horizontal circumference, 49½ centimetres; naso-occipital arch, 34 centimetres; binauricular arch, 34 centimetres; height of the orbits, 4½ centimetres; breadth of the orbits, 5 centimetres; transverse diameter (measured with callipers), 12·2 centimetres; anteroposterior diameter, 16·2 centimetres; suboccipito-frontal, 16·2 centimetres; distance between the two external angular processes, 11·4 centimetres; and height of the frontal bone, 11·8 centimetres. The cephalic index was therefore 75·3. Certain ridges on the cranium were well marked; the superior temporal line stood out along the whole side of the skull; the superior curved line of the occipital bone could be felt and the external occipital protuberance was of the size and shape of a marble. There were no definite parietal eminences. The internal condyle of each humerus was very prominent and this enlargement was symmetrical; the internal condyle of each femur was also large and there was the slightest possible amount of genu valgum. The proptosis could be well seen in the photographs (see illustrations). Quite two-thirds of the globe were in front of the orbital margin; a little pressure on each lid caused still more proptosis and pain; there was more proptosis in the right eye than the left and it could be moved laterally by the fingers but this was painful. Vision was good; there was no nystagmus. Hearing was good. There was external strabismus on both sides but the left eye was the most affected The movement of the right eye, when acting alone, was impaired in the inward direction and slightly so in the upward direction. Similarly there was impaired movement with the left eye acting alone but the movements

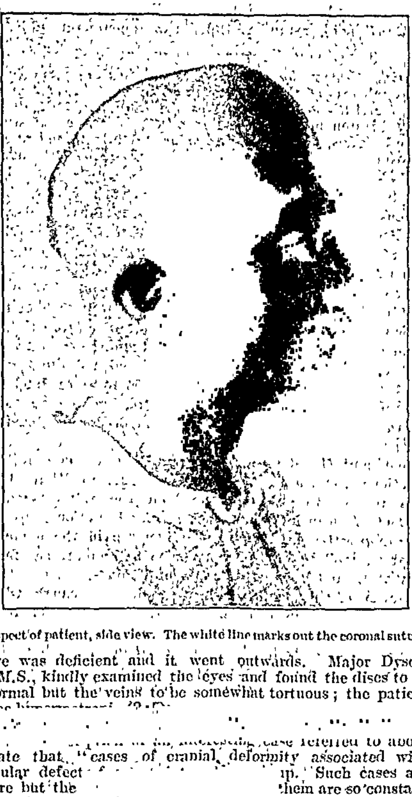
FIG. 1.



Aspect of patient, front view.

of the left eye inwards were slightly more impaired than on the other side. When both eyes acted together the left eye did not follow an object moved towards the right and when the object was to the left the right eye did not move beyond the median line. Bilateral movement of the eyes downwards was normal but on looking upwards movement of the left

FIG. 2.



Aspect of patient, side view. The white line marks out the coronal suture.

eye was deficient and it went outwards. Major Dyson, I.M.S., kindly examined the eyes and found the discs to be normal but the veins to be somewhat tortuous; the patient

interesting case referred to above state that "cases of cranial deformity associated with ocular defect ip. Such cases are rare but the them are so constant that it appe these defects are dependent on, or at any rate are closely related to, the deformity of the skull. The variety of cranial deformity most commonly found in these cases is oxycephaly." The case which is described above is an interesting example of this type of cranium and the proptosis and external strabismus give the patient a curious and noticeable physiognomy. But it differs from the case described by Mr. *Dodd and Mr. McMullen in showing no appreciable mental* defects and in slightly less cranial deformity. The cause of the early obliteration of the lambdoid suture which produced the exaggerated growth in the vertical direction is quite obscure and rickets is discarded by the authorities in the consideration of the etiology, but in this case the existence of the exostoses in the position of the external occipital protuberance and the humeral condyles and the slight genu valgum are points of interest.

POPLAR AND STEPNEY SICK ASYLUM DISTRICT.—The report of the managers of this district for the year which ended on Lady-day, 1904, shows that in the various institutions of which they have control there were 921 patients, as compared with 896 last year. The analysis of diseases shows that bronchitis, heart troubles, rheumatism, and ulcers are greatly in excess of other affections. There was one case of Hodgkin's disease in the Bromley Asylum.

Medical Societies.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on June 21st, Dr. H. Angus, the President, being in the chair.—Dr. T. M. Legge, H.M. Medical Inspector of Factories, read a paper on Sclavo's Serum Treatment of Anthrax in Man. Dr. Legge stated that his attention was first called to the work of Dr. Sclavo in a

had since received, through the kindness of Dr. Sclavo, professor of hygiene in the University of Sienna, some 60 tubes of the serum, but before venturing to bring the matter before the society and asking the members to use the serum he had endeavoured to sift the evidence on which treatment by its means was based. Evidence as to the possibility that passive immunity might be conferred on man had been obtained as the result of Sobernheim's analogous experiments *in the case of sheep.*[1] *Sobernheim found that by adopting* the method (originally acted on by Dr. Sclavo) of combined active and passive immunising treatment (simultaneous inoculation of serum and virus) he was able to produce a high degree of active immunity in sheep and that the serum of such animals contained specific protective bodies against anthrax. Supported by the Chamber of Agriculture of Saxony he had tested and proved the success of the method on 2700 cattle in anthrax infected districts. As soon as the inoculations were commenced further outbreaks of the disease ceased to arise. Already in 1895 Dr. Sclavo had been able to show (1) that sheep brought to a high degree of active immunity could furnish a serum active against anthrax, and (2) that this serum showed prophylactic and curative powers against anthrax in rabbits. In order to obtain a more powerful serum he instituted comparison of the efficacy of *the serum obtained from the sheep, the goat, the horse, the* ass, and the ox. It was from the ass that he obtained the most powerful serum and in a recent communication to him (Dr Legge) Dr. Sclavo still regarded the ass as the most suitable animal from which to obtain anti-anthrax serum. In view of the experimental results showing the curative power of the serum and its innocuousness when injected in large doses into animals Dr. Sclavo turned his attention to the treatment of external anthrax in man and the first case was treated by means of the serum in June, 1897. In a paper[2] dated 1903 Dr. Sclavo gave details as to age, occupation, situation of pustule, medical practitioner treating, verification and result of 158 out of cases, all which had been treated with the serum up to time of reporting. The fatality in these 164 cases was 6·09 per cent. as compared with 24 per cent. for the figures *published for the whole of Italy and* 26 per cent. for 211 cases of industrial anthrax reported to the chief inspector of factories in the years 1899–1903. The figures were very far, he thought, from giving an accurate idea of the therapeutic value of the serum. In several instances the treatment was not tried until all hope from every other form had been given up. Even in some of the fatal cases extraordinary improvement for a time occurred. The conclusions which Dr. Sclavo drew from his work in consideration of the results hitherto obtained were that: (1) the serum was innocuous even in large doses; (2) it could be well borne even when *introduced into the veins; (3) no case* taken in an early stage and of moderate severity would be fatal if treated with the serum; (4) by its means some cases might be saved when the condition was most critical (he narrated one case in which a woman recovered after bacilli were found both in the blood and urine and another in which they were present in the urine); (5) when injected into the veins it quickly arrested the extension of the œdematous process so as to reduce notably the danger of suffocation which was present in many cases when the pustule was situated on the face or the neck; (6) if used early enough it reduced to a minimum *destruction of the tissues when* the pustule was localised and thus diminished risk of deformity; and (7) persons attacked appeared to become convalescent almost at once. The dose of serum recommended in ordinary cases was 30 to 40 cubic centimetres subdivided into three or four injections subcutaneously into different parts of the abdomen and followed in 24 hours if there had been no improvement by further injections of from 20 to 30 cubic centimetres. In every grave case he recommended endovenous injection, preferably into one of the superficial veins on the back of the hand, of ten cubic centimetres followed in an hour or two where no improvement was shown by another similar dose.—Dr. J. H. Bell, Dr. H. J. Campbell, and Mr. W. H. Horrocks made remarks on the paper and Dr. Legge replied.—Mr. C. F. M Althorp showed specimens of Ovarian Tumours.

Reviews and Notices of Books.

Progressive Medicine. Edited by HOBART AMORY HARE, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital. Vols. I. and II., 1903. London: Rebman, Limited. Vol. I., pp. 450; Vol. II., pp. 437. Price 15*s*. per volume.

AS our readers are probably aware this publication consists of a quarterly digest of advances, discoveries, and improvements in the medical and surgical sciences. Vol. I. contains six contributions. The first is by Dr. C. H. Frazier on the Surgery of the Head, Neck, and Chest. Some interesting remarks are made on operative procedures in cases in which the heart has been wounded. The results obtained from several sources clearly show that there is a larger percentage of recoveries after operation than when only palliative treatment has been adopted. The surgical treatment of pulmonary tuberculosis is also commented on, but the general trend of opinion seems to be that up to the present operative interference has not met with much success. The next article is headed Infectious Diseases, including Acute Rheumatism, Croupous Pneumonia, and Influenza, and is written by Dr. J. B. Herrick. The value of the antitoxin treatment of diphtheria is discussed. Although the vast majority of practitioners are convinced of the good results obtained by means of the antitoxin there still appear to be some sceptics who maintain that the whole question is yet unsettled. Hueppe, for instance, at a meeting of the Prague Medical Society, argued that the benefit arises from the fact that when the serum is used the physician feels that he has done his best and therefore lets the harmful local treatment alone. That this opinion does not represent that of the Prague school is shown by the vigorous defence of antitoxins by Ganghofner, Epstein, Salus, Langer, and others. Dr. F. M. Crandall writes on Diseases of Children and makes some interesting observations on the morbid conditions affecting the newly born infant and he also gives a *résumé* of the contributions which have appeared on infant feeding. The section on Pathology has been intrusted to the able hands of Dr. Ludvig Hektoen. Amongst other matters he gives a good summary of recent investigations in regard to cytotoxins, agglutinins, and precipitins. The recent advances in laryngology and rhinology are considered by Dr. A. Logan Turner, and those in otology by Dr. R. L. Randolph.

Vol. II. commences with an article on the Surgery of the Abdomen, including Hernia, by Dr. W. B. Coley, who considers that there is a strong tendency on the part of operators to combine the distinctive features of a number of operations for hernia into a single operation which, they reason, must give better results than any of the methods if carried out as originally proposed. The review of advances in gynæcology is written by Dr. J. G. Clark who gives an extensive digest of the latest papers upon all phases of cancer of the uterus. He considers that this is the one gynæcological disease which has resisted all forms of treatment and "stands as a reproach to the abdominal surgeon." His remarks upon inflammatory affections of the pelvic viscera are also worthy of note. Dr. Alfred Stengel gives an account of the work which has been accomplished in reference to diseases of the blood and ductless glands, the hæmorrhagic diseases, and metabolic diseases. Under this heading are included observations on diabetes, gout, myxœdema, exophthalmic goitre, and Addison's disease. The last contribution in this volume is on Ophthalmology by Dr. Edward Jackson. The whole publication maintains the high standard which always characterised it.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. Second Report of the Anti-malarial Operations at Mian Mir, 1901–1903. By Lieutenant S. R. CHRISTOPHERS, M.B. Vict., I.M.S. New Series, No. 9. India: Office of Superintendent of Government Printing. 1904. Pp. 37. Price 10 annas or 1*s*.

THE author of this monograph first briefly refers to previous reports on the same subject by the Royal Society's Commissioners and by Captain S. P. James, I.M.S. The main results of the work undertaken in 1902 were found to be that the cleaning of the banks in itself did not prevent the breeding of anopheles in the watercourses and "oiling" in addition with kerosene was found necessary; that no reduction in the *anopheles Rossii* was noticeable, although the *anopheles culicifacies* was to an extent diminished; and that the fever season in the bazaar was delayed and shortened The results obtained also by Captain James in 1902–03 with reference to the destruction of anopheletes over a wide area were without effect, for in May, 1903, the anopheletes were as abundant as ever.

Lieutenant Christophers then details an account of his operations from July to November, 1903, in Mian Mir. With respect to the operations on the water-courses, the fact of cleansing their sides having been found to be quite inoperative in stopping the increase in the number of larvæ, "oiling" was had recourse to regularly, at first every week and later at intervals of 12 days. After the institution of this regular oiling nymphæ were caught with the greatest rarity in the channels so treated. It was found, however, that unless the vegetation fringing the watercourses was first removed "oiling" was rendered impracticable. In order to reduce the cost the experiment of emulsifying the oil with soap solution was tried, with the result that a more perfect film was produced and its effectiveness was almost doubled. These experiments in the laboratory did not, however, coincide with their use in the canals where the pure oil was found to be somewhat more effective. The author then proceeds to note the results obtained on miscellaneous breeding places by drainage and the filling up of pits and sheets of water around the barracks, bazaars, and bungalows within the area experimented upon. He found that in spite of these measures a good many breeding places were left which had to be searched for and removed, such as the water in small cement tanks, kerosene tins, and earthenware water-pots. These were dealt with once a week. Lieutenant Christophers, however, holds them to be of little comparative importance. The operations directed against rain-formed pools are next narrated. These consisted in superficial drainage, filling with earth, baling out, and "oiling"; on the whole, surface drainage was found to be the most effective and satisfactory of all operations.

In Part III. the results are detailed. It was found that the number of larvæ in the area experimented upon showed no tendency to diminish in spite of repeated wholesale destruction and that with reference to the diminution of the common anopheletes in Mian Mir none perceptibly occurred as regards the *anopheles Rossii*, whilst it was difficult to come to a conclusion respecting the *anopheles culicifacies*. The result of Lieutenant Christophers's experiments in regard to the effect of anti-culicidal measures against anopheletes is thus in direct variance with hitherto recorded results. With regard to the effect on malaria, he found the onset of the fever season to be postponed but that after the first two months no effect was apparent.

In Part IV. certain points in the biology of mosquitoes are detailed, such as were found in connexion with the swarming of certain species; with their flight, it being found that at Mian Mir they traversed three-quarters of a mile to reach an abundant food-supply; with the spread of adult anopheletes; with the time of pupation and hatching; and with the effect of heavy rain and of desiccation on anopheles larvæ.

In Part V. the question of treatment by quinine is dealt with. A very distinct reduction in malaria followed its administration where the latter was strict, but the author does not hold that as a routine practice it is of much value owing to the difficulties in its employment. When given to native children, however, its effect upon the prevalence of enlargement of the spleen was very distinct.

Lieutenant Christophers thus shows his conclusions to be in close accordance with those arrived at by Captain James in the first report. He holds that "gradual but permanent improvement in the health of stations by well-directed sanitary reforms, wherever these can be carried out, will in the end yield the best results."

The Prevention of Disease in Armies in the Field. By ROBERT CALDWELL, F.R.C.S. Eng., D.P.H. R.C.P.S. Edin. & Glasg., Major R.A.M.C. London: Baillière, Tindall, and Cox. Pp. 182.

WE welcome this excellent work. There are not many such books on this important subject nor are there many characterised by the conveyance of so much valuable matter in so brief and portable a compass as has been contrived by the author. It embraces the outcome of his experience in Egypt and South Africa. Enteric fever is first treated. Major Caldwell's earliest experience of this disease in an epidemic form was at Korosko in 1885 and 1886. He had previously left this camp in July, 1885, with a clean bill of health as regards enteric fever but on his return there in the succeeding winter he found that the disease had developed during the winter months to a most serious extent. To account for the epidemic the author concludes that the bacillus typhosus arose by transformation of the colon bacillus which then found a suitable medium in the basic nitrates and residue of unreduced organic matter in the sandy soil and was subsequently disseminated by means of dust and of flies. No enteric fever was found previously in the neighbouring villages of the fellaheen nor would it appear to have been water-borne. Again, in regard to South Africa Major Caldwell, who served in the Ladysmith relief column, holds that the enteric fever therein arising was due to the polluted soil surroundings, the enteric bacillus being swallowed with the dust, the food, or the water.

With regard to dysentery the author points out that although this disease may not appear so promptly as enteric fever consequent on pollution of the soil, yet when once it has appeared it will persist much longer. He holds that the essential cause owes its origin to some pre-existing organism in the alimentary canal and that then after attacking its own host it is voided in the fæces, from which the next victim is attacked. He also draws attention to the probably acquired infection developed from primary diarrhœa, an observation fully according with the experience gained in Afghanistan in 1878-80. The various conditions associated with diarrhœa are next detailed, as to its origin from food, water, dyspepsia, chill, and a probable specific organism. The facts relating to various other diseases—e.g., simple continued fever, dyspepsia, contagious ophthalmia, pneumonia, dengue, and malaria—conclude this portion of the work.

Administrative matters affecting the health of troops in the field form the next subject for discussion. The bell tent is deservedly condemned; there is no ventilation worthy of the name and when the "flies" are down and the door is laced up the interior, as the author remarks, suggests that of a fœtid oven. It is also a most inefficient protector against heat or cold and by excluding the sunlight the bactericidal powers of the sun are lost. The author draws attention also to the spread of infection by blankets, by clothing, and by stretchers; with regard to the last-named an admirable adjustable waterproof cover, invented by him to prevent such contamination, is figured. The danger of aerated waters owing to previous defilement in some way or other of the bottles is pointed out and the objection to prolonged occupation of the same camping grounds is also alluded to.

The author next treats of sanitary measures in the field; he shows how important a matter is the inspection of men as to their fitness to serve at the front. At the outbreak of war it is natural that our countrymen should be anxious to serve and so during the Boer war the reservists constantly concealed the existence of ailments from the eyes of the civilian practitioners and were thus passed although hopelessly unfit for the fatigues of a campaign. The necessity of avoiding camping grounds in localities swarming with flies is insisted on. Next follow considerations how to guard against soil pollution in connexion with tents, latrines, and camp refuse, and in regard to this part of the subject it may be mentioned that the author has himself devised a very efficient camp and refuse destructor. In the disposal of the excreta of patients in field hospitals it must be remembered, as the author states, that it is necessary to sterilise the excreta of enteric fever patients beforehand. Firth and Horrocks have shown that the enteric bacillus can survive 74 days in moist soil. This, however, must always be a source of difficulty in a mobile camp. Hence all serious cases of illness must be at once removed from the fighting line. In his field hospital the author ordered all vessels for the reception of the excreta to contain a 10 per cent. solution of carbolic acid. He, however, expresses the doubt whether the germicidal fluid ever came into sufficiently intimate contact with these excreta. As it is laid down that the germicide should be intimately mixed with the excreta for an hour before burial by the authorities we certainly share his doubt.

The book deals with many other subjects on which limits of space forbid us to dilate, such as diet, marches, clothing, medical inspection, and the prevention of malaria and parasitic diseases. In conclusion, we congratulate the author on the production of a work which every officer of the Royal Army Medical Corps should possess.

Tuberculosis. By NORMAN BRIDGE, A.M., M.D., Emeritus Professor of Medicine in Rush Medical College. London, Philadelphia, and New York: W. B. Saunders and Co. 1903. Pp. 302. Price 6s.

THE substance of the lectures on "Medical Tuberculosis" delivered by the author in Rush Medical College during the past three years is embodied in this work. The book is divided into 18 chapters and a fairly satisfactory account is given of pulmonary and laryngeal tuberculosis. Dr. Bridge is more successful in the clinical description than when considering the etiology and pathology of the disease. Some of his statements can scarcely be taken as accurate. For instance, in speaking of the bacillus tuberculosis he says: "In different atmospheres the number of organisms inhaled by an adult person varies from probably half a dozen to several hundred every minute of life." Man is probably naturally immune to tuberculosis but the resistance of the human species would have to be very strong to overcome such [illegible] are [illegible]

Again, we cannot agree with the following statement and explanation: "A patient will often make a sudden slight improvement after a moderate hæmorrhage. We were at a loss to understand why this was so until it was discovered that the blood outside the vessels has a power more destructive to microbes than that inside. ...... It is true that it [the blood] also washes away some of the products of the disease and helps to get them out of the body, which is useful so far as it goes." The author's views, too, on the formation of fibrous tissue in a tuberculous lung are also rather vague. "It is my belief that fibrosis is incited to some degree by the motion of the lung: the greater the motion and violence from the respiration the greater the fibrosis; the more quiet the lung, the less of this process." The chapters on the Symptoms, Physical Signs, and Diagnosis of Tuberculosis are, on the other hand, well worthy of study. They exhibit a thorough knowledge of the disease from a clinical standpoint and many hints are given which will be found of value in actual practice. Dr. Bridge constantly associates the physical signs with pathological conditions, which is the correct way of obtaining a true picture of the course of the disease. His remarks on treatment are also interesting and his directions as to diet may be followed with advantage. He lays due stress on the prophylaxis of tuberculosis and he points out the educational advantages of sanatoriums in teaching patients affected with the disease how they can to a great extent prevent the spread of the malady.

Lectures on Clinical Psychiatry. By Dr. EMIL KRAEPELIN, Professor of Psychiatry in the University of Munich. Authorised translation from the German, revised and edited by THOMAS JOHNSTONE, M.D. Edin., M.R.C.P. Lond. London: Baillière, Tindall, and Cox. 1904. Pp. viii.—308. Price 10*s.* 6*d.* net.

NO apology is needed for the reproduction in English of any part of Professor Kraepelin's works on psychiatry. His classical "Lehrbuch der Psychiatrie," which embodies the soundest and most advanced knowledge of the day in psychological medicine and of which a new German edition in two volumes has just been issued (1904), constitutes the high-water mark of science in this direction and must be regarded as indispensable for all alienists and students of mental disease. The present volume of clinical lectures is different in that it consists of a series of lessons mainly clinical and descriptive of the various types of insanity, eminently practical in character. and taking but little account of metaphysics and anatomical pathology. The introductory lecture on melancholia is followed by others in which the maniacal-depressive insanities and adolescent insanity are discussed. Then follow other lectures dealing with states of depression in general paralysis, epileptic insanity, maniacal excitement, katatonic insanity, the megalomania of general paralysis, and alcoholic insanity. Next, by a natural transition, the toxic group of insanities is taken up and the insanities which follow acute (infectious) diseases, the varieties of mental delirium, and puerperal insanity are described at some length. The fifteenth and sixteenth lectures deal with the predominantly delusional forms of insanity of the young—paranoia and paranoid dementia præcox—which at the present day are attracting much attention, and many interesting facts and data are brought together in these chapters with regard to these affections. The concluding half of the book is occupied with such subjects as the different forms of insane delusions, chronic alcoholic insanity, morphinism and cocainism, the final stages of general paralysis and of dementia præcox, imbecility from coarse cerebral lesions, epileptic imbecility, senile insanity, traumatic insanity (following head injuries), idiocy, imbecility and cretinism, and the psychoses which lie on the borderland of insanity—hysteria major. the insanity of obsessions and morbid impulses, and criminal and other morbid (including sexual) perversions of personality. In the course of 29 lectures Professor Kraepelin has given us within the compass of a moderately sized volume a series of instructive studies and clinical pictures of the various forms of insanity which for interest, information, philosophic insight, masterly grasp of the subject, and clearness of exposition will rank with the famous lectures of Charcot and will probably long remain unsurpassed in psychiatric medicine.

Intestinal Parasites as Factors in the Mortality of Prisoners in Cannanore and Rajahmundry Jails. By C. F. FEARNSIDE, M.A., M.B. Aberd., Major I.M.S. Reprinted from the *Indian Medical Gazette*, vol. xxxix. (No. 4, April, 1904). Pp. 35, with clinical chart.

THE object of this pamphlet is to draw attention to the prevalence of the ascaris lumbricoides on the west coast of India as shown by experience in the Cannanore Jail. The health of the prisoners there has been unsatisfactory for many years; the total death-rate has been uniformly high and that from bowel affections has generally been considerable. Only during the last three years included in the series of observations has there been a steady reduction in the mortality generally and especially in that due to bowel complaints. The reduction is believed to be due to the recognition of the fact that the ascaris lumbricoidet is excessively prevalent in this part of India and thas to its presence may be traced many of the diseases which have caused mortality in previous years. A post-mortem examination on a case of diarrhœa with anæmia and dropsy revealed 37 worms at the ileo-cæcal valve and it occurred to the author that they were the cause of the intractable character of the case. Acting on this idea regular resort was had to anthelmintics in the treatment both of prisoners and of prison subordinates, with the result that the number of cases of dysentery was reduced from 144 in 1892 to 10 in 1896, the number of cases of muco-enteritis from 77 in 1892 to nine in 1896, and that of diarrhœa from 79 to one. The prevalence of the parasite on the west coast is doubtless due to the damp climate of Malabar. Other worms which are very common on the coast are filaria sanguinis hominis, oxyuris vermicularis, tricohcephalus dispar, and the ankylostoma duodenale. Man is not the only host in this district infested with these parasites; in the crow and other birds tapeworms and ascarides are very common. Major Fearnside draws attention to the great importance of the presence of the ankylostomata in malarial or other cachexias. He says that they bleed patients who can ill afford to lose the blood and set up local congestions and erosions of the bowel which cause a catarrh and thus retard the proper assimilation of the food and recovery. It is this secondary effect of the presence of the ankylostoma that he looks upon as most injurious. The pamphlet is an interesting one; but why has Major Fearnside not published his observations earlier? The death-rates of the Cannamore Jail are quoted from 1881 to 1896.

THE CREMATION SOCIETY OF ENGLAND.—No. XVII. of the Transactions of this society has just been published and naturally contains a reference to the death of the late Sir Henry Thompson, Bart., one of the founders of the society and its president from its inception 30 years ago. During the year 1903 143 cremations took place at Woking, a number considerably less than in previous years, but it should be noted that the Golder's Green crematorium commenced operations at the close of the year 1902 and was, therefore, in competition with the Woking crematorium during the year 1903. The total number of cremations which have taken place at Woking to the end of 1903 is 2515. Notwithstanding the decrease in the number of cremations carried out at Woking during the past year the receipts were slightly more than the expenses of the society.

THE LANCET.

LONDON: SATURDAY, JULY 9, 1904.

What Constitutes Live Birth?

AMONG the most important cases in which medical evidence is put forward in courts of law are those where the issue depends upon the answer to the question, "Was the child born alive or not?" This importance may arise in the case of the mother of a dead child who is being tried upon the capital charge owing to her having been alone when the child was born and from medical evidence being consequently the only evidence obtainable as to the fact of life; in civil cases it may be due to there being rights to property depending upon the result. In the cases which arise in the civil courts and which are of far less common occurrence than the criminal trials there are more frequently witnesses as to the details of the birth other than medical men, but these are likely to be under the influence of sympathy with one side or the other, so that the weight of impartiality is added to the scientific value of the medical evidence. In these circumstances it is a matter for some regret that neither the legislature nor the judicial bench has ever laid down an authoritative definition of live birth for the purpose of legal proceedings. The recently constituted Central Midwives Board in framing rules for the guidance of midwives in cases of stillbirth had to supply them with a definition collated from the summing-up of various judges. There was no other course open to them. Yet the question is one of no less importance than that of mental responsibility which the House of Lords discussed in M'NAUGHTON'S case and upon which they called together the judges to advise them. For the guidance of midwives who are to notify stillbirths to the local supervising authority the Central Midwives Board has laid down that "a child is deemed to be stillborn when it has not breathed or shown any sign of life after being completely born," and as the board's rules have been approved by the Privy Council this may be said to be an authorised, if not a legal, definition of stillbirth as opposed to live birth.

Dr. STANLEY B. ATKINSON, a medical man who has been called to the bar, contributed an exhaustive article entitled "Life, Birth, and Live Birth" to the April number of the *Law Quarterly* which has been reprinted in the form of a pamphlet. This article contains a variety of dicta from the summings-up of judges in cases where questions of birth have been discussed from various points of view and the diverse opinions thus collected for comparison show how difficult it is to arrive at a just conclusion in such a matter. An important part of the task set is to draw a line at some point in the often protracted period of parturition the crossing of which must be accomplished before the new human being can be deemed to have entered the world. Until he has crossed that line he is neither to possess property nor to have a life the wilful taking away of which can be charged as murder, and yet before he has crossed it, wherever it is fixed, he will still have been physiologically alive and his life will have been such that he could have been deprived of it by the act of others. With regard to this vexed question as to when the life of a human being, as such, is to be deemed to begin it will be seen from the numerous cases cited by Dr. ATKINSON that judges, whatever they may hold to be the law, do not always approve the view that "complete birth" is necessary in order to constitute a live child. "Complete birth" implies that the child is entirely external to the mother but it is not necessary to "complete birth" that the placenta should have come away or that the umbilical cord should have been severed. Fortunately, the women who after giving birth to children conceal or destroy them do not study the law and are usually not in a condition deliberately to evade it, otherwise dangerous results might follow from their realising that the killing of the child when still partly in the mother's body could not be charged as murder. That this, however, would be in consonance with the accepted view of the law is well known. Professor MEYMOTT TIDY, among scientific writers, called attention to it in his work on "Legal Medicine," citing a case occurring in 1841 in which an accused person, who had cut off the head of a child that was in process of being born, was acquitted of murder. Among the cases cited by Dr. ATKINSON in which judges have expressed doubt or disapproval as to such a theory of separate existence is one in which Mr. Justice WILLS, a judge of great experience, characterised it as "very unsatisfactory" and as "enabling women to escape punishment on account of a pure technicality which is contrary to medical knowledge on this point." Mr. Justice WRIGHT on another occasion seems to have told a jury that "the true test of separate existence in the theory of the law, whatever it may be in medical science, is the answer to the question whether the child was carrying on its being without the help of the mother's circulation. If 'Yes,' then it had a separate existence even though it might not be fully born. If 'No,' it had no such separate legal existence" In that case the jury acquitted the prisoner, so that no question could be raised as to whether the definition formulated for their guidance was to be regarded as of universal acceptance or not.

It is not, however, only the moment at which life as a human being begins which is not satisfactorily defined, but the "signs of life," the presence or absence of which are to be taken as proof of its existence, require definition also. With regard to this Dr ATKINSON observes: "Many judicial statements may be cited as to the nature of the test of the consummation of live birth. Repeatedly is the proof of either 'existence' or 'circulation' insisted upon, seldom is that condition defined, even parenthetically." It is a matter of some importance for medical men that they should know in studying medical jurisprudence or in qualifying to give evidence in a case in which their testimony is required where the line between existence and non-existence as a human being is to be drawn. It is also of importance for them that they should know what faint traces of the performance of functions associated with life are to be deemed proof that "life" was once present. It may be observed that trials of the kind indicated must always present great difficulties of fact to judges and still more to juries, whatever advantage may be derived from a clear statement of the law. They are cases in which, of all others, the presence of the medical assessor would be of advantage to the judge and the 12 men whose combined opinion now decides so many weighty and abstruse questions.

The Fairs at Wigan.

The ancient borough of Wigan, in Lancashire, is apparently to be congratulated on the possession of an institution, or organisation, or whatever it may most appropriately be called, which might with great advantage be introduced into many other localities. Its official style is "The Wigan and District Ratepayers' Emergency Association" and its business seems to be mainly that of subjecting the municipal authorities to the steady pressure of local public opinion in order at once to encourage them in well-doing and to restrain them from undertakings not likely to be beneficial to their constituents. A recent example of the useful activity of the association has been furnished by a letter which it has addressed to the mayor of Wigan, embodying a resolution to the effect that there is no longer any need for the Wigan fairs which have hitherto been held twice annually, in May and in October, and declaring that these fairs, in the opinion alike of the association and of the majority of the townspeople and ratepayers, are detrimental to the best interests of the town and to the health of the inhabitants. It is pointed out that since its inclusion in the list of "large towns," the death-rates of which are tabulated weekly and published by the Registrar-General, Wigan has gained an unenviable notoriety by reason of its high mortality and the association considers the fairs to be very objectionable on sanitary grounds, to say nothing of the question from the standpoint of public morality. The association therefore expresses its hope that the mayor and council of the borough will see their way to terminate the evils complained of by abolishing the fairs and by thus putting an end to the disorders which they occasion. The power of actual abolition is, we believe, vested only in the Home Secretary, but there can be no doubt that this power would at once be exercised if sufficient ground were shown by the local authorities.

It is, of course, more than probable that the representations thus made by the association are entirely justified by the facts of the case, inasmuch as fairs which have survived the circumstances first calling for their establishment have always displayed a tendency to degenerate into nuisances of a very grave description. As originally founded, they were of great public convenience by collecting together, at times when roads were bad and when travelling was difficult or dangerous, large numbers of the buyers and sellers of various commodities and, still more frequently, by affording facilities for the wide distribution of the products of local industries. Even in quite recent times, for example, the once famous "Goose Fair" of Nottingham was a very important mart for cheeses of the Stilton type, which were thence carried into all the northern parts of the kingdom, and other great fairs have fulfilled similar purposes with regard to other commodities. At one time the supply of Scottish cattle to the south was largely dependent upon the drovers and dealers who went in large numbers to the great fair at St. Faith's, near Norwich; Weyhill fair was the great centre of the south of England sheep trade; the fairs of Horncastle, of Howden, and of Woolbridge were the places at which young horses chiefly passed out of the hands of the breeders; and nearly all the Irish cattle destined for export changed hands at Ballinasloe. Fairs of this kind, with special objects of their own, survived most of those which were of merely local reputation, which had never fulfilled any more important purpose than that of the periodical gathering together of general commodities for the convenience of the inhabitants of the district, and which were deprived of their sole *raison d'être* by the uprising of numerous market towns, by the extension and improvement of roads, canals, and railways, and by the development of the general postal and commercial systems of the kingdom. The origins of the local fairs thus rendered superfluous were, in many cases, lost in the mists of remote antiquity; many, however, if not most of them, had been seized upon in feudal or mediæval times as a means by which profitable privileges could be conferred upon some individual, community, or corporation, to whom or to which certain tolls became thenceforward payable. Towns which had suffered during war were sometimes thus rewarded if the side which they had espoused were victorious, an example being the privilege of holding a free fair which was granted by Edward III. to the town of Burnley. Other fairs were held under the control of religious bodies and frequently became monopolies of the most rigorous and oppressive character. London shops were compulsorily closed during the days on which the Abbot of Westminster's fair was open, and the Bishop of Winchester was entitled to forbid the transaction of ordinary business in Winchester and in Southampton during the continuance of St. Giles's fair—a period which was extended from three days to 16 by a charter granted by Henry III. It is fairly certain that powers of this kind committed to ecclesiastics would not be permitted to rust or to languish from disuse, and that fairs supported by such privileges must have entailed serious loss upon all the established or stationary traders in their vicinity.

The fair of greatest interest to the medical profession is undoubtedly the once famous Bartholomew's or "Bartlemy" fair, which, like St. Bartholomew's Hospital, was founded in Smithfield in 1133 by Rahere, a monk who was described by Stow as "a pleasant witted gentleman" and who filled the not very monastic office of minstrel and jester to Henry I. According to an account in the Cotton MSS., Rahere "ofte hawnted the kyng's palice, and amo'ge the noyseful presse of that tumultuous courte, enforsed hymselfe with jolite and carnal suavite: ther yn spectaclis, yn metys, yn playes, and other courtely mokkys, and trifyllis intrudyng, he lede forth the besynesse of alle the day." Rahere founded a monastery of which he was the original prior and concerning which there is a curious record of a free fight between the sub-prior and canons, on the one hand, and Boniface, Archbishop of Canterbury, and his followers on the other, with reference to the Archbishop's claim to act as visitor. To this monastery, according to STOW, HENRY II. granted the privilege of a "faire to be kepté yeerly at Bartholomew-tide for three daies, to wit, the eve, the day, and the next morrow"; but, in course of time, the period became extended to as much as 14 days. In 1614, on account of the filthy state into which the soft ground was trampled by the great concourse of people, the City authorities spent £1600 in paving Smithfield; in spite of this improvement, NED WARD, in 1669, describes the fair as "ancle deep in filth and nastiness." The moral filth seems at least to have kept pace with the physical for, in 1703, at the close of a good deal of description in which agricultural implements are called by their shortest names, we read that "this is not an ark, like NOAH'S, which received the clean and unclean; only the unclean beasts enter this ark, and such as have the Devil's livery on their backs." By that time the fair had become an intolerable nuisance and many endeavours were made by the Lord Mayor and Aldermen first to shorten its duration and then to abolish it, but these were not entirely successful until 1855 when it came to its end. It was at one time the chief cloth fair of the kingdom but its period of usefulness covered only the first two or three centuries of its existence. Its history is analogous to that of all similar institutions, and the preamble of the Act 34 Vict. c. 12, by which fairs are now controlled, declared that many of those then existing were "both unnecessary and productive of grievous immorality." We trust that the representations of the Wigan Association may be favourably received alike by the borough authorities and by the Home Office.

The Literature of Scientific Papers.

WE received recently from the publishers an admirable little book by Professor T. CLIFFORD ALLBUTT, Regius Professor of Physic in the University of Cambridge, dealing with the literary composition of scientific papers,[1] and having read it carefully we wish that it could be made compulsory upon every member of the medical profession to do the same. In his preface Professor ALLBUTT points out that his book consists only of comments on the more frequent or more eminent defects of scientific essays, his experience being obtained by perusal, as a matter of duty, of some ninety or hundred theses, presented in the course of every year by candidates at the University of Cambridge for the degrees of Bachelor or Doctor of Medicine. He further states that his notes upon these defects are of an unsystematic and occasional character. The notes must be admitted, we suppose, to be of this casual sort, "for he himself has said it," but we should not have so described them; at any rate, despite the limitations indicated by the title of the book and by the author's verecundity, we have from his pen an excellent and suggestive tract upon the whole art of literary composition as applied to our language. We, like Professor ALLBUTT, have to peruse as a matter of duty a large number of scientific essays and we find that he has summarised, and well-nigh with completeness, within the compass of his 150 pages, the various faults of style, arrangement, and presentation that are most commonly to be found in the writings of medical authors. But he has done more than this. As a matter of fact, these same faults are to be discovered in the writings of all technical authors of the present day, whether their special engagement be in medicine, in law, in physics, or even in history. It is a notable fact that the scientific workers in all these departments of life, whose labour is and must be conducted with exactness, who deal with measurements of the smallest diameters and dates of the utmost precision, and whose whole working practice is a protest against inaccuracy, are as a class singularly inaccurate writers. Their dates and their measurements will stand scrutiny, but not the words in which they bring their facts to public knowledge. They know what they mean to say, but often they do not say it. At other times they say it, but in such an ambiguous and involved manner that the value of their teaching is discounted heavily. What Professor ALLBUTT has found in his experience of theses at the University of Cambridge, what we have found at the offices of THE LANCET, is illustrated in every technical paper in the United Kingdom, and it does not seem to us that other nations are ahead of us. Elaborate scientific papers reach us daily which have been printed in the reports of various societies and the archives of various learned bodies; the majority of them are marred by the failings that are prevalent in the theses of the Cambridge candidates.

Professor ALLBUTT'S book contains two sections, an introductory chapter which deals rather with the usual procedures of the writers of academic essays and a second chapter which is an essay on the art of literary composition, the teaching being here mainly in the nature of counsel as to the things to be avoided. In the first chapter he introduces us to his own methods of composition, rightly pointing out that every writer must have his personal plan of work. Professor ALLBUTT'S plan is not given by him as an example of one that it would suit all to follow but we are sure that the glimpse afforded into what we may call his "desk manners" will be valuable to most of our readers. It will bring home the fact, so well known to a few who have learned it by experience and apparently so little known to the scientific world, that something beyond a mass of information and a desire to publish the same goes to the making of a good book or a good essay. In the second chapter Professor ALLBUTT alludes to most of the pitfalls that lie in the path of those who fare forth into English composition without proper equipment, whose general culture supplies them with no proper standards of comparison, whose vocabulary is scanty, whose ear is ill-trained, and whose taste is faulty. Here we find pointed out the errors of those unhappy people who use fine language when uninspired by fine thought, who employ words of obvious derivative meaning in contradiction to that meaning, who lose themselves in the mazes of their metaphors, who cannot appreciate that force and clearness are lent to a sentence by the arrangement of the words, that sentence—who, in fact, shovel on to paper in the first phraseology that occurs to them all that they have to say, and, knowing their own intentions, are bewildered to find themselves misunderstood. Professor ALLBUTT does not draw his examples, either those he would have us imitate or those he would have us avoid, from medical literature, but has made his teaching far pleasanter and more entertaining by going to general literature for them. But as medical journalists we thank him for inculcating two lessons:—(1) that the rules of English prose, the methods of English style, and the graces of literary art can be as well employed upon a scientific theme as upon a romantic one; and (2) that without attention to the methods of writing and the arrangement of material a scientific work, however solid the attainments of its author, must lose much of its value. Professor ALLBUTT makes it apparent that to write well is not with many people an instinctive performance but rather the result of considerable industry, training, and application. ROBERT LOUIS STEVENSON, whose literary style, as displayed in popular romance and whimsical tales of adventure, brought home to the English public more than any modern writer has done the possibilities of our own tongue, described himself in an autobiographical note as "a sedulous ape," meaning that with the greatest industry he had imitated the style of all those of his predecessors whom he admired before he evolved a style of his own. It is a similar spirit of industry that Professor ALLBUTT would suggest as worthy of their consideration to the writers of scientific papers. We all know that style is nothing without matter, that arrangement is idle without facts—that, in short, it is essential for a man to have something to say before he considers how to say it—but when a scientific author has a message to deliver he should consider more carefully than he does at present the form in which he will deliver it. Pains expended in this way will gain for him a hearing from many ears that hitherto have been deaf.

---

[1] Notes on the [illegible] of Scientific Papers. By T. Clifford [illegible], F.R.C.P., F.R.S., F.L.S., F.S.A., [illegible] University of Cambridge. Price 3s. [illegible] London.

It is disconcerting for those of us who say, and think, that the general level of culture in the medical profession is rising, to find Professor ALLBUTT'S criticism of the literary capacity of medical men founded entirely upon the perusal of theses submitted by graduates in medicine, who are generally graduates in arts, of one of the older universities. The difference between the education of the university graduate and that of the diplomate of a corporation is supposed to be that the former has obtained, and profited by, his larger opportunities for general culture. It is allowed that in many instances in the British scheme of medical education the graduate is in no sense the scientific superior of the diplomate. Is he superior in general culture? Our experience is a large one and we know that we are right when we say that as a rule the graduates of the older universities display the advantages of a broader range of knowledge and a better preliminary grounding. If at the University of Cambridge these advantages have not led to any first-hand acquaintance with literary methods it is certain that no other young medical men or young scientific men, taken as a whole class, have higher literary capacities. Most of the candidates for the degrees of Bachelor of Medicine and Doctor of Medicine at the University of Cambridge will read Professor ALLBUTT'S book and profit by it, and thus will remove from their University what seems to us to constitute a reproach. But we heartily recommend the book to all our readers. Professor ALLBUTT is an acknowledged master of elegant, precise, and good English. Apart from their scientific value his writings have claims to be considered models of prose, so that he has that best of all positions from which to be heard when he speaks of literary methods and literary style—he has employed them both with distinguished success.

Annotations.

"Ne quid nimis."

THE MEDICAL DIPLOMATES' SOCIETY OF LONDON.

THE Medical Diplomates' Society of London has been established for the purpose of meeting the natural desire of its members to obtain admission to a "final examination in *medicine*" which shall entitle them to a medical degree and shall thus remove the "serious disabilities" under which they labour by not possessing the title of "Dr." although their work is of a standard which would elsewhere than in London obtain for them a medical degree. We have received from the new society a copy of its rules and also a circular addressed *urbi et orbi*, asking for the "advice and support" of those into whose hands it falls and signed by the president of the society, Dr. F. J. Smith, of the London Hospital. By the rules of the society the qualification for membership is the possession of any diploma conferred either by the Royal College of Physicians of London or the Royal College of Surgeons of England; and there may be honorary members, not necessarily qualified as above, but of "recognised position and distinction in the medical profession." The declared object of the society is to promote the "professional advancement" of its ordinary members "by holding meetings, by providing opportunities for social intercourse, by such other means as the executive committee may approve from time to time, and by endeavours to obtain admission to an examination for a degree in medicine conferred by a British University." The language of the rule, it will be observed, differs from that of the circular, which sets forth that the contemplated examination is to be a "final" one in "*medicine*" only. The society, in short, represents the desire, the natural desire, of a certain number of "diplomates" to become entitled to call themselves "Dr." or "M.D." and to be affiliated to a "British University." We do not believe there is the least prospect that any British university will consent to give its degrees in medicine on any different basis of general attainment than is required for degrees in any other faculty. The position of the medical student in London is a peculiar one and its anomalies are now attracting much attention. He has the finest opportunities in the world for obtaining clinical instruction. He has so many chances of receiving adequate scientific education that embarrassment is produced by the duplication and reduplication of lecturers and laboratories. And yet it is exceedingly difficult for him to obtain the title of "Dr." which among the public is regarded as the hall-mark of a medical man. The Medical Diplomates' Society of London may assist in the cause of reform and so benefit succeeding generations of London students. But with regret we have to record our impression *that the action of the members must be regarded as altruistic.* We do not think it possible that they will obtain for themselves the title of "Dr." from any British university though their professional attainments are known to warrant their ready acceptance as *alumni*.

THE NATIONAL LEAGUE FOR PHYSICAL EDUCATION.

A CORRESPONDENT has sent to us a copy of *Sandow's Magazine* for July, directing our attention especially to a paragraph under the heading "National Physical Education. Doings of the Month. Edited by M.D.," in which the writer says: "I have had several letters from various parts of the country asking various questions on the subject of national physical education, which will receive attention in another part of the magazine, but one from Mr. S. O. Oliver, of Newcastle-on-Tyne, would, I think, be better dealt with here. Mr. Oliver suggests that it would stimulate both pupils and teachers alike in their physical welfare if a national league of physical education was formed. The idea seems to be a good one and I thank my correspondent for the suggestion, to which I am giving my closest consideration, and I hope in our next issue to be able to place a rough draft of some such scheme before my readers." Certainly "M.D." and Mr. Oliver would appear to be by no means up to date and not to have watched the course of events. In THE LANCET of July 18th, 1903, a letter under the heading "A National League for Physical Education" was published from Sir Lauder Brunton, suggesting the foundation of such an association and shortly afterwards a dinner was given by a well-known host at the Athenæum Club to a representative company of guests, including the Bishop of Ripon, Lord Grey, Sir Henry Craik, Sir Frederick Maurice, and several members of the medical profession especially interested in the matter. The proceedings at this dinner were referred to in our own columns on July 25th and also at greater length in the *Manchester Guardian* on July 23rd, 1903, which also printed a sketch of a draft scheme. This scheme, as our readers are well aware, is now being developed and has received the adhesion of many of the most important leaders of the clergy, law, medicine, education, and science, as well as of a good many Members of Parliament and others. We are, of course, not aware whether "M.D." is a member of the profession but we are sorry to see the names of two medical men given at length as writers of articles in a magazine which admits the advertisements of quacks to its columns. Mr. Sandow, who in some ways has done good service to the cause of physical education, is ill-advised in not exercising a closer supervision over the contents of his *Magazine*.

THE ORBITAL MUSCLE.

A CAREFUL description of the musculus orbitalis in man and many mammals is given by F. Groyer in the Vienna *Sitzungsberichte der Kaiserlichen Akademie der Wissenschaften* (Band cxii., 1903, Abtheilung iii., p. 51). The credit of being the first to recognise the presence of this muscle in man, though its existence had long been known in animals, and to establish its muscular character belongs to H. Müller. Previously to his researches it was uncertain whether it was of a fibrous, an elastic, or a muscular structure and hence it was merely termed the "membrana orbitalis." Gurlt, indeed, before Muller at one time described it as a muscle but subsequently withdrew this statement and regarded it as an elastic structure. Differences have also existed as to its extent and its action, some, like Eckbard, maintaining that it contributes to the movements of the lids as well as acting on the globe. Harling, again, considers it to be only a part of the periosteum of the orbit. The results of Groyer's own observations he thus sums up. The musculus orbitalis consists in all mammals of unstriated muscle and its size is inversely proportional to that of the osseous walls of the orbit, completing the wall of the orbit where the bone is deficient. It is continuous with the periosteum of the orbit. The muscular fibres may be disposed in one or two lamellæ. The musculus palpebralis consists of either striated or unstriated muscle; in aquatic mammals it is composed of striated muscle, in terrestrial mammals of unstriated muscle, and in the latter classes it appears to play an important part in the propulsion of the tears. The transversely striated palpebral muscle arises in common with the recti muscles, a part accompanying each rectus and being attached to the sclerotic and a part entering the lid. The palpebral portion of the orbital muscle which is connected with the inferior, internal, and external recti is composed exclusively of unstriated muscle but that portion connected with the superior rectus forms a special muscle, the levator palpebræ superioris, the posterior part containing striated fibres, the anterior splitting into two lamellæ one of which forms a tendon and the other a layer of smooth muscle and forming the musculus palpebralis superioris. The unstriated musculus palpebralis arises both from the recti and from the levator palpebræ superioris by elastic fibres. In aquatic mammals the levator palpebræ superioris is identical with that portion of the musculus palpebralis which arises from the rectus superior. The musculus orbitalis and that portion of the musculus palpebralis which is composed of unstriated muscle are united posteriorly by an elastic membrane which represents the second origin of the musculus palpebralis. Muscular fibres extend to the nictitating membrane from each of those segments of the musculus palpebralis which arise from the internal and inferior recti. These fibres may be associated with fasciculi from the musculus levator palpebræ. The muscular fibres passing to the membrana nictitans are transversely striated in all aquatic mammals but completely unstriated in all terrestrial mammals. The nerve-supply of the musculus orbitalis is the same in all mammals, both aquatic and terrestrial, and proceeds invariably from the sympathetic. The musculus palpebralis when consisting of striated muscle is innervated by the same nerve as that distributed to the corresponding rectus but when it is composed of unstriated muscle it is supplied by the sympathetic.

A RECENT ANALYSIS OF THE STRAWBERRY.

THE strawberry is a great favourite and the present season has produced an enormous quantity of excellent sound fruit. The question of the dietetic value of the strawberry is frequently discussed and we are inclined to disagree with the very commonly asserted opinion that the strawberry should be forbidden to sufferers from gout seeing that its richness in certain salts tends to render the blood alkaline and to lower the acidity of the excretions. According to analysis which we have recently made the average composition of the 1904 strawberry is as follows:—

Water	89·500	per cent.
Soluble salts (including free acid)	1·146	,,
Lime and iron salts	0·137	,,
Proteid	0·800	,,
Sugar	5·800	,,
Oily matter	0·154	,,
Cellulose and seeds	2·463	,,

Next to water the chief constituents are free acid (with acid salts), sugar, and fibre. The total acidity calculated as tartaric acid amounted to 0·822 per cent. A strawberry contains a greater proportion of water than does milk, which on the face of it may seem odd since the strawberry appears to be solid as compared with milk. As to nutritive value the strawberry can count *for little unless we regard* the sugar, which amounts to one-half the total solid matter, as valuable in this respect. This sugar, it may be remarked, however, is fruit sugar or lævulose which is more easily assimilated by patients suffering from diabetes than are other sugars, so that strawberries on this account are frequently allowed to sufferers from mild types of that disease without any harm ensuing. On the whole, however, the strawberry is consumed rather for the sake of its moisture, sweetness, and flavour than for any value that it may possess as a food, and according to analysis this value is small. The salts are doubtless slightly laxative, while the indigestible seeds and the fibre, when consumed in large quantities, are calculated to increase peristalsis and thus to be serviceable in sluggish action of the bowels. The mineral salts of the strawberry contain quite a large proportion of potassium, phosphoric acid, and iron, so that the view that an abundant diet of strawberries may have the effect of a tonic is not without some reasonable basis. The colouring matter of the strawberry is very soluble both in water and alcohol, the solution giving a characteristic absorption spectrum, a dark band occurring in the green. The colouring matter contains iron in an organic form. Tannic acid has little or no action upon the strawberry, so that the "strawberry tea" is justifiable dietetically. The strawberry is remarkably soluble in alkaline solutions such as may be taken to represent the alkaline digestive juices of the intestine. In fact, practically the whole of the fruit is easily and rapidly soluble in weak alkali, excepting, of course, the seeds, which, moreover, are rejected by the organism. The oil extracted from the strawberry has a most attractive flavour and its amount, calculated on the dried fruit, is not inconsiderable. The unripe or unsound strawberry shows a much higher proportion of acid than does the sound fruit, a fact which amply accounts for the consumption of unsound fruit giving rise to diarrhœa and colic.

IN THE MATTER OF PATENT MEDICINES.

TREATED as a purely academic question the inquiry addressed to us by a correspondent in a letter published at p. 111 is not one difficult to answer. He asks whether a medical man knowing the formula of a patented proprietary article can have it made up as a prescription and, further, whether he may do so if it can only be made by a special patented process. To this reply may be made that the proprietor of any manufactured article protected by letters patent or of any process so protected is entitled to defend his rights against infringement and that he is likely to take steps to do so if he can discover that such infringement has taken place. When, however, the principles applicable to the enforcement of patent rights are applied to concrete cases of proprietary medicines there are matters of some importance which have to be taken into consideration. The law does not seem to be affected by the question of public policy involved in assigning monopolies with regard to the treatment of disease to certain persons. In a case relating to the sale of poisons under the Pharmacy Act of 1868[1] it was apparently taken for granted that the protection of medicinal compounds under the Patent Acts was a recognised practice, for in that case it was suggested that "chlorodyne" was exempted as a "patent medicine" from the operation of sections of the Pharmacy Act regulating the sale of poisons and the court only refused to accept that view on the ground that chlorodyne was merely a proprietary article in respect of which no letters patent had been granted. If, however, in theory combinations of drugs of a novel character can be invented and patented, in practice it will not be found that this often occurs. The man of science does not desire to create monopolies in connexion with the practice of medicine for his own benefit and the owner of the Miraculous Pill or Wonder-working Potion has not, as a rule, got a patentable article to register. He has obtained possession of a formula which is possibly useful and effective but which at the same time is one which medical men have used before and for which no novelty can be claimed. In these circumstances he does not take out letters patent for his nostrum but merely assigns to it a fancy name which he registers as a trade-mark and under which he advertises his wares. In this manner he can protect his trade without endangering it by making known how his so-called "patent medicine" is compounded. Were he to take out letters patent he would run the risk of others acquiring easily possession of his secret; it would in many cases be very difficult for him to detect them in using it and an attempt to prevent them might involve costly and possibly unsuccessful litigation. It would be awkward for the owner of the Miraculous Pill to have proved in open court that his formula was a simple one which any medical man might have prescribed and therefore not entitled to be the subject of patent rights and that in any case the pill's intrinsic value was about one-hundredth part of its sale price. We are not sufficiently aware of the circumstances in which our correspondent "Inquirer" is placed or of his intentions with regard to the patented article concerning which he writes to advise him upon the concrete case which he, no doubt, has in his mind. We can only say that the infringement of the rights conferred by letters patent can be prevented by legal process and that medicinal compounds or processes for their manufacture do not, as such, form any exception to the rule.

RADIUM AND DIAMONDS.

THE influence of radio-emanations on the constitution of matter is very curiously illustrated in some recent experiments made by Sir William Crookes. According to the results, if radium comes to be a common commodity amongst us some dismay may be caused to those who wear diamonds on finding that the carbon crystal under the influence of radium threatens to return to its less attractive form of graphite or crystalline black carbon. On the other hand, radium may turn out to be a "diamond improver." It is well known that radium emanations possess the property of darkening transparent bodies upon which they impinge and now Sir William Crookes has shown that this also holds good in the case of diamonds. The emanations convert not only the surface into graphite but alter also the colour of the body of the stone. It is therefore suggested that this observation may prove to be of commercial importance. For example, "if off colour stones can be lightened their value will increase, while if the prolonged action of radium is to communicate to them a decided colour they would be worth much more as fancy stones." This may add considerably to the business of the jeweller who, for a consideration, might undertake to submit "off jewels" to burial in radium for a season.

THE ROYAL ALBERT ASYLUM FOR IDIOTS, LANCASTER.

THE Royal Albert Asylum at Lancaster has cost in the last 40 years nearly £200,000 and has just received an important addition to its means of usefulness by the building of a fine block of industrial schools and workshops. The cost of these has been nearly £7000, of which sum Mr. Herbert Storey, the High Sheriff of Lancashire, has generously given £5000. The original workshops were inadequate owing to the increased number of patients capable of industrial training and from the rise of other buildings had become dark and unsuitable. Mr. Storey therefore offered to furnish a permanent memorial of the coronation of the King, as his father, the late Sir Thomas Storey, in like manner erected in the grounds the

Storey Home for 40 feeble-minded girls as a memorial of Queen Victoria's Diamond Jubilee. In the new buildings are shops for shoemaking, basket-making, cabinet-making, and wood-carving. There are tailors' shops, a brush and mat-makers' shop, and printers' and bookbinders' shop, while the basement is divided into a large playroom and an upholsterers' and sashcord makers' shop. Much attention has been given to the ventilation and lighting. The opening by Mr. Storey took place on June 24th in the presence of a large number of friends and supporters of the asylum. Sir J. T. Hibbert, chairman of the central committee, said the asylum had its beginning in November, 1864, when Mr. James Brunton of Morecambe offered to give £2000 "for the establishment of an asylum for the reception, care, and training of idiot children." Now there are 627 feeble-minded inmates of both sexes. The opening ceremony was brief. The door having been unlocked, Lord Muncaster, the Lord Lieutenant of Cumberland, formally accepted the gift. At the luncheon which followed, Mr. Storey in replying to the toast of his health said that while he did not anticipate that the new workshops would turn out persons so skilled as those endowed with complete faculties he looked forward to the training in habits of industry enabling the patients to earn their living. Sir John Hibbert said they still wanted a building for the reception of 20 or 30 new-comers where they might undergo a sort of quarantine. He felt sure that the money would be forthcoming before the end of the year and we may all hope that he will prove a true prophet.

NERVOUS DISEASES AND SYMPTOMS OF THE SCHOOL AGE.

UNDER the above title Dr. T. S. Clouston, President of the Royal College of Physicians of Edinburgh, contributed a paper to the *Parents' Review* for July which is of considerable interest to both medical and lay readers. He begins with a quotation from Dr. W. Leslie Mackenzie that "the nervous system of the growing child is the cardinal physiological problem of the educational life" and then proceeds to describe in simple, non-technical language some of the more important phases of the activity of the nervous system and their derangements. The nervous symptoms occurring in children during the school age—that is, from six to 18 years—he discusses under five headings—namely, disturbances of the muscular system originating in the brain, comprising epilepsy, chorea, hysterical fits, stammering, and squint; disturbances of sleep, especially insomnia; disturbances of nutrition the result of nerve changes; sensory disturbances, notably the different varieties of headaches; and lastly, mental disturbances. This section of the paper, as might be expected from Dr. Clouston, is most suggestive and forms an interesting *résumé* of some very important facts relative to the abnormal psychology of childhood. We are glad to notice that at the very outset Dr. Clouston states emphatically that "there are many popular misconceptions about 'mental symptoms' and moral defects which sensible parents and teachers should particularly avoid." He points out that these symptoms should be regarded in a great many cases as the equivalents in the mental sphere of headache and other such derangements on the sensory side. Impulsiveness, for example, which is merely a defect of mental inhibition or control, he points out as varying in some children with their state of health; again, laziness and stupidity may in many cases be nervous and not moral defects and many other perversions are to be regarded as mere symptoms of mental derangement or non-development. It is very important to realise that they should be carefully and judiciously treated on physiological and medical lines rather than by pedagogic and disciplinary methods. We can commend Dr. Clouston's paper to the notice of all who are interested in the education of children, more especially the weakly and backward. His general aims may be gathered from his closing paragraph which we quote in full: "The doctor and the physiologists nowadays strongly incline to the education theory of turning out a good all-round animal to face up the hazards of life; and the highest and most useful faculty, the one most worth cultivating, is inhibition—self-control. That can only be attained in most cases through health of body and soundness of mind."

ASSOCIATION OF BRITISH POSTAL MEDICAL OFFICERS.

THE annual dinner of this association was held on the evening of July 1st at the Whitehall Rooms of the Hôtel Métropole, London, Dr. J. Walton Browne, the President, being in the chair. A large number of medical officers attached to the Post Office and their guests were present but the gathering was not perhaps quite so numerously attended as in previous recent years. After the loyal toasts the President proposed the health of the Right Hon. Lord Stanley, C.B., M.P., His Majesty's Postmaster-General. Lord Stanley made a sympathetic reply and alluding to the lengthy toast list observed that medical men were evidently very unselfish seeing that they wished good health to so many people—a fact which must necessarily be to their own disadvantage. He also humorously referred to the fact that although he had only been recently appointed to the office of Postmaster-General those who had drawn up the programme had arranged that the title of the next song should be "Good Bye." The other toasts were "The Imperial Forces," proposed by Mr. Edward Bond, M.P., and responded to by Colonel S. Raffles Thompson; "The Secretary and Other Executive Officers of the Post Office," proposed by Sir Thomas Roe, M.P., and replied to by Mr. H. Babington Smith, C.S.I., the secretary to the Post Office, who, like the Postmaster-General, referred to the excellent work done by the medical officers; "The Association of British Postal Medical Officers," proposed by Mr. Eugene Wason, M.P., and responded to by the President; and "Our Guests," proposed by Dr. John Dunlop and replied to by Sir Dyce Duckworth. The proceedings were enlivened by pleasant music, songs being admirably rendered, in the intervals between the toasts, by Miss Annie Bartle, Miss Ethel Bevans, and Mr. Franklin Clive. The Imperial orchestra played a selection during the dinner.

THE CHILDREN'S COUNTRY HOLIDAYS FUND.

THE rôle which pure air plays in health and its conservation is now recognised on all hands and so is the fact that country life and scenes have a valuable effect upon the mind. Especially is this latter the case with children. If proof were required it is only necessary to be present at the return of a batch of poor children to one of the great railway termini in London after a sojourn in the country. Their complexions tell the tale of improved health and their tongues run ceaselessly in the discussion of their new ideas. There are several societies the object of which is to provide an annual country holiday to the poor children of London but the support which they receive from the charitable public is not at all commensurate with the undoubted good which they do. Among them is the Children's Country Holidays Fund the chairman of which has just received from Sir William J. Collins a letter which has been forwarded to us for publication. From it we take the following extracts: "Of some 800,000 children attending the public elementary schools of London only a small proportion can in any year enjoy the happy fortnight in a cottage home for which your fund provides the opportunity. Even in the case for which a change is urgently necessary there will, I fear, be many disappointments unless the public will give a larger measure of support to your efforts and those of the ladies and gentlemen who give the fund such invaluable voluntary assistance. ...... To those who know as I do the home conditions of many of our humbler citizens in Central, East, and South London the possibility of any reduction in the number of children who will have a chance of this happy and health-giving fortnight in the country this year can only be contemplated with dismay and profound regret." Sir William Collins, who is chairman of the education committee of the London County Council as well as surgeon to two well-known charities, has had exceptional opportunities for knowing the conditions under which the poor of London live and we trust that his testimony as to the needs of some of London's little ones will have the effect of bringing to the coffers of the Children's Country Holidays Fund the money which is so urgently needed. Subscriptions may be sent to the offices of the fund, 18, Buckingham-street, Strand, London, W.C.

PRIZE-GIVING AT ST. MARY'S HOSPITAL.

Dr. W. B. Cheadle presided over the distribution of prizes to the successful students of St. Mary's Hospital Medical School on June 29th. The ceremony was held in the Medical School of St. Mary's Hospital and the prizes were given away by the Lord Chief Justice of England, Lord Alverstone, who, addressing himself to the students, observed that in no profession more than the medical was it essential to maintain the highest ideal of honour, and, moreover, there was no profession which brought out more the good qualities of a man. He particularly emphasised the importance of concentrating the mind upon the particular case presented for consideration and he reminded his hearers that in the practice of medicine there was scope for individual thought and independent research. Passing on to the discussion of the use and abuse of athletic sports he gave it as his opinion that sports ought not to be made the object of life but should be viewed as means whereby a man's life-work could be better done.

THE MYSTIC ELEMENT IN MEDICINE.

Professor F. Dercum of Jefferson Medical College, Philadelphia, in an interesting address delivered in May last at the twentieth anniversary of the foundation of the Philadelphia Neurological Society, dealt with the subject of mysticism in medicine. Since time immemorial superstition and magic have played a rôle in the treatment of disease. 4000 years ago the Egyptian healers subjected their patients to mysterious "passes" and manipulations, after which the patients were enveloped in the skins of sacred animals and conveyed to holy places where the treatment might be completed. The practice of uttering words and phrases in a hysterical delirium by healers supposed temporarily to be "possessed" of a god or spirit is also of very ancient date. The priestesses of Delphi and of other Greek temples did so in ancient times and the Shamans of Siberia and the priests of many savage and barbarous tribes still practise rites in which they pass into somnambulistic and hysterical states and give utterance to words which are regarded by the people as inspired by the god or spirit invoked, or do extraordinary deeds to cure disease. Thus in Siberia, says Professor Dercum, the priest, after his invocations, will "suck the part of the body of the patient which aches the most and finally take out of his mouth either a thorn, an insect, a stone, or some other object, which he then asserts to have been the cause of the pain." Rubbing and massage have been used for centuries but the ancients combined them with movements and passes which were believed to have a magic virtue. Cælius Aurelianus prescribed friction by the hand for the cure of pleurisy and gave instructions for the manipulation of the insane and of epileptics. It is said that "when the manipulations were carried to excess the patients fell into a [hypnotic] lethargic sleep." Agrippa in the sixteenth century and the famous Paracelsus and van Helmont were among the earlier advocates of the doctrine of an animal magnetism. Magnets were used to heal illnesses, the theory of animal magnetism and the healing of the sick by the aid of magnets being constituents of the popular belief of the Middle Ages. Metals were also regarded by many as being possessed of mysterious virtues in the treatment of disease, an old belief traceable through Paul of Ægina and Galen to Aristotle. Lenoble in 1754 and Hall in 1774 are said to have effected wonderful cures by magnets, the theory of these operators being a special development of the popular belief to the effect that the heavenly spheres exercised a magnetic influence over human bodies and that the correct use of magnets was the only means of rectifying those ailments which arise from disturbance of the animal magnetism of the body. Many of these beliefs and practices, says Professor Dercum, were the prelude to the methods developed by Mesmer during the century following. While mesmerism was at its height three schools of animal magnetism sprang up. The first, that to which Mesmer himself belonged, asserted that the effects obtained were due to physical agencies alone. The means employed were friction, touches, passes, and grasping, the resulting phenomena being explained on the theory of a magnetic fluid or ether passing from the magnetiser to his subject or *vice versâ*. The school of Barbarin maintained that faith was the principal factor required, in consequence of which they were known as spiritualists. To their minds all physical means were merely accessories. The third school, that of the Marquis de Puysegur, occupied a middle position, explaining the results obtained by physical or psychical means as the case required. The adoption of hypnosis and its scientific study by the schools of Paris and Nancy three decades ago are regarded by Professor Dercum as the beginning of the scientific era, the work of Charcot, Richer, Liebault, and Bernheim having gone far to explain the nature (physiological process) of hypnotism and its relationship especially to the great neurosis hysteria. More than all others these two schools have succeeded, he considers, in placing the practice of hypnotism on a scientific basis. The special development of metallo-therapy, however, Professor Dercum regards as having proved nothing beyond the fact that "suggestion" plays the most important part and that the metals do not act by producing "emanations" or other subtle effects comparable with invisible radiations.

THE EVOLUTION OF THE "REST" TREATMENT.

Dr. S. Weir Mitchell of Philadelphia has published in the *Journal of Nervous and Mental Disease* for June an interesting account of the mode in which he was led to evolve the method of treatment of neurasthenia and other nervous disorders by rest. Very often it is found that discoveries made through accident prove to be of value and this, says Dr. Mitchell, was the way his discovery was made. During the Civil War between the North and South States "a great many cases of what we called acute exhaustion fell into the hands of Dr. M——, Dr. K——, and myself. These were men who, being tired by much marching, gave out suddenly at the end of some unusual exertion and remained for weeks, perhaps months, in a pitiable state of what we should call to-day neurasthenia." In these cases occurring in the war the neurasthenia, says Dr. Mitchell, came on with strange abruptness. It was more marked in intensity "and also more certainly curable than are most of the graver male cases of to-day." Complet rest and plentiful diet usually restored their strength and enabled them to return to the front. In 1874 a lady with marked neurasthenia came under care. She was a tall, large, gaunt woman who had borne several children in rapid succession and who had overworked herself in charitable and other work to an extent far beyond her strength. Her weight was about seven stones, she was pale and anæmic, and could not climb the stairs owing to general weakness. Her appetite was feeble and capricious and she was only able to retain and to digest her meals if she lay down in a noiseless and darkened room. But any disturbance, excitement, or effort caused nausea and immediate rejection of the meal. "With care she could retain enough food to preserve her life and hardly do more." Staying in bed for a week brought on symptoms of violent emesis, with rejection of food and consequent extreme exhaustion. Having seen cases of tabes and rheumatic stiffness of joints improved by massage it occurred at this juncture to Dr. Mitchell that massage might also prove beneficial to his patient and that in this way her muscles might be exercised without fatigue. He also hoped that the appetite would be restored by this means and employed a nurse to massage his patient systematically several times a day. A few days later the electric (galvanic) current was applied to the muscles. Entire rest and seclusion were insisted on during this period. In ten days the patient began to improve. "The woman had found a new tonic, hope, and blossomed like a rose. Her symptoms passed away one by one." Her diet was steadily increased and malt with phosphates of iron was given regularly and daily. "I had found, in short," says Dr. Mitchell, "that with this combination of seclusion, massage, and electricity I could overfeed the patient until I had brought her to a state of entire health. In two months she gained 40 pounds and was a cheerful, blooming woman, fit to do as she pleased." Simple rest as a treatment had been suggested but not in cases of neurasthenia, adds Dr. Mitchell. Massage has a long history and is daily coming into wider use in treatment.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

THE annual provincial meeting of the Incorporated Society of Medical Officers of Health was held at Newcastle-on-Tyne on July 2nd and was presided over by Dr. Joseph Groves. A paper was read by Dr. J. J. Boyd, medical officer of health of South Shields, in which he gave the results of investigations which he had made into the distribution of scarlet fever in different parts of South Shields during the 12 years 1892–1903. These investigations were of a very painstaking and thorough character and might well serve as a basis for observations in other towns. Dr. Boyd divided the borough into 86 districts made up practically of the enumeration districts as defined for the census of 1901. For each of these districts he obtained from the last census returns full details of population including the numbers living at different age periods, together with the number and size of the houses. He was thus able to calculate an attack rate corrected for age periods. With regard to the three years 1901–1903 he gave full information as to each of the 86 districts with respect to the corrected attack rate, the percentage of cases isolated in hospital, the proportion of tenements of less than five rooms, the number of persons per room, the social condition of the inhabitants, and the physical features of the localities, and with regard to the nine years 1892–1900 he gave the uncorrected average annual attack rate. The conclusions to which he came as the result of these investigations were that the physical features of a district did not apparently appreciably influence either the extent of the endemicity of the disease or its spread in epidemic times, that very poor class districts were apparently less subject to the disease than were more respectable neighbourhoods, and that hospital isolation if carried out to a high degree, that is to say, the isolation of at least 50 per cent. of the total cases, lessened the prevalence and spread of the disease. Dr. Boyd thought that the figures for the whole 12 years amply proved that in South Shields the isolation of scarlet fever in hospital had not resulted in an increased prevalence of the disease nor had it intensified its virulence. Mr. H. E. Armstrong said that he so thoroughly believed in the isolation in hospital of cases of scarlet fever that he had persuaded the Newcastle city council to expend £53,000 upon extensions to the existing hospital. Dr. T. Eustace Hill, Mr. Herbert Jones, Dr. John Taylor, Dr. W. W. Stainthorpe, Mr. T. Wilson, Dr. J. W. Hembrough, Mr. J. G. Willis, and the President also took part in the discussion and spoke approvingly of hospital isolation. At the close of the meeting the members of the society with their friends lunched together and in the afternoon a visit was paid to the Newcastle fever hospital at Walker-gate and to Tynemouth. At the fever hospital Dr. Sydney G. Mostyn, the medical superintendent, gave a demonstration of the steriliser for infected excreta which was designed in 1894 by Mr. Armstrong and Mr. W. George Laws, M.Inst.C.E., the city engineer. The essential features of the steriliser are the admission of steam into a cylinder into which the excreta have been discharged and the cooling of the contents of the cylinder after sterilisation and prior to being emptied into the sewer. Suitable non-return valves are provided completely to close the cylinder to all openings except that of the steam-pipe. Steam can also be admitted to the interior of the soil-pipe and of the waste-pipe from the slop sink.

MULTIPLE NEURITIS DUE TO GONORRHŒA.

MULTIPLE neuritis is a rare complication of gonorrhœa. At the meeting of the Société Médicale des Hôpitaux of Paris on June 23rd M. Ménetrier described a case which is important not only on account of the intensity of the symptoms but also because it appears to be the only one in which a necropsy was made. A man, aged 46 years, was admitted to hospital on Oct. 27th, 1903, suffering from gonorrhœa and complaining of pains and of almost complete powerlessness of his four limbs, which confined him to bed. The patient had previously had several attacks of gonorrhœa which lasted five or six months. More than six months before admission the present attack of gonorrhœa began and a month later he commenced to feel weak in his legs. This symptom was most marked at the end of the day under the influence of fatigue. It increased and at the end of September he had to give up work. At the same time he felt pains in the lower limbs which were so severe as to prevent him from sleeping. The pains extended to the upper limbs, in which also power was lost but to a much less degree than in the lower limbs. On admission the discharge was still in full activity. The pus was almost completely composed of mononuclear cells and contained an abundance of gonococci. The lower limbs were so weak that the patient could not raise them from the bed and the muscles, particularly the adductors, the quadriceps, and the muscles of the calf, were atrophied. The sensibility of the lower limbs was blunted. Deep pressure was very painful, the muscles being hyperæsthetic. Pressure on the nerves was equally painful. There were also spontaneous pains and tingling in the lower limbs. The knee-jerks were absent. In the upper limbs the paralysis was less though the muscular masses of the arm, forearm, and hand were atrophied. Movements of the upper limbs were feeble and incoördinate. Sensory troubles were also less severe; cutaneous sensibility was preserved and the muscles were less tender than in the lower limbs. In the trunk the muscular atrophy was less marked but the patient had great difficulty in sitting up. Faradic irritability was entirely lost in the lower limbs; in the upper limbs it was preserved but a strong current was necessary in order to obtain a reaction. In the forearm the flexors responded more readily than the extensors; the extensor indicis responded feebly and the common extensor of the fingers not at all. On the following days the paralysis of the upper limbs increased; soon movements of the arms became impossible and those of the forearm became limited to flexion of the fingers. Then the paralysis spread to the trunk and neck; the patient could not sit up or maintain his head in position when it had been raised from the bed. He lay inert but always complaining of sharp pains, principally in the upper limbs. His general condition became worse and a bed-sore rapidly formed over the sacrum. Finally he became feverish, the tongue became dry and dirty, the respiration became difficult, and fine subcrepitant râles were heard at a spot at the right base. Death from broncho-pneumonia took place on Nov. 13th. At the necropsy the brain showed only congestion of the pia mater. The pia mater of the cord was also congested. The large nerve trunks (sciatic nerve and brachial plexus) as well as the smaller nerves (branches of the radial and crural nerves) appeared normal to the naked eye but were preserved for histological examination. The muscles of the thigh and forearm, though diminished in volume, were of good colour and showed no changes to the naked eye. The lungs were consolidated at the bases. On section a drop of pus trickled from the orifices of the bronchi. The liver was large and yellow and appeared to be fatty. The kidneys were much congested, soft, and tumefied. The urine contained in the bladder was purulent and the mucous membrane was congested. Microscopic examination of the brain was negative. In the cord the only lesions found were chromatolysis, globular swelling, and vacuolar changes in some of the cells of the anterior cornua. These changes occurred principally in the cervical and lumbar regions. In the nerves pronounced changes were found at the peripheral ends which became less marked as the central end was approached. Not a single fibre in the radial nerve was normal; the myelin was broken up or absent and the axis cylinders were irregularly swollen, fragmented, or destroyed. The lesions were purely degenerative, there being no multiplication of nuclei. A branch of the crural nerve showed similar changes. The fibres of the brachial plexus and sciatic nerve were almost intact, showing only fragmentation of myelin in a few without changes in the axis cylinders. The lesions in the spinal cord may be explained as due to the same toxic cause which produced the neuritis but possibly they were secondary to the latter. Marinesco has shown that such cellular changes may result from multiple neuritis and also from traumatic neuritis.

THE WRECK OF THE EMIGRANT SHIP "NORGE."

ONE of the most lamentable disasters at sea that has occurred during recent years took place in the North Atlantic Ocean on June 28th, when the Danish emigrant ship *Norge*, carrying a crew of 71 men and nearly 700 passengers, consisting, so far as is at present known, of Swedes, Danes, and Russian Jews, struck on Rockall, a rock 75 feet high, about 140 miles distant from St. Kilda, the nearest land. The *Norge* belonged to the United Steamship Company of Copenhagen and left that port on June 22nd for New York. The survivors have been rescued in different boats and landed at Stornoway, Aberdeen, and Grimsby, but it is feared that more than 500 lives have been lost. As yet no authentic details of the cause of the catastrophe have been received; it is only known with certainty that at eight o'clock on the morning of the disaster the passengers felt a shock and almost immediately the vessel began to sink. Stories of gallant heroism on the part of the crew, only a few of whom were saved, and of the passengers are told by the survivors. It is said that the boats were improperly managed, some of them being overcrowded and others only half full. This, if true, was no doubt due to the excited state of the passengers, but the fact that only a few of the crew were saved shows that those in charge of the vessel accepted to the full their responsibilities.

FOOD PRESERVATIVES.

A COMMITTEE has recently been sitting in New York in order to collect evidence as to adulteration and more especially as to the use of preservatives in food. The committee consisted of Dr. William Frear (chairman), Dr. E. H. Jenkins, Professor M. A. Scovel, Professor H. A. Weber, and Dr. H. A. Wiley. In discussing the use of preservatives Dr. Frear is reported to have said: "The testimony of the manufacturers has generally been that such goods cannot be packed without preservatives without a certain percentage of loss. ...... The best opinion seems to be against the use of preservatives as a general proposition as injurious; but, on the other hand, it is argued that the quantity used is so small as to be harmless. The manufacturer seems to believe that it ought to be enough if all goods containing preservatives were plainly labeled so that the consumer could see for himself and take the responsibility for what he is taking into his stomach." It is expected that the Secretary of Agriculture in a few months will be able to promulgate a set of standards which will define what is meant by purity in foods and what constitutes adulteration.

THE USE OF RADIUM IN SECTION CUTTING.

THE electrification of sections as they "peel off" the microtome in section cutting is often a source of trouble which leads in fact to the sections adhering to each other and to the knife of the microtome. Professor Henry Dixon, of the Botanical Laboratory, Trinity College, Dublin, bearing in mind the property of radio-emanations of discharging an electrical condition, ingeniously applies this property to the prevention of this source of annoyance. In a note in *Nature* he points out that these undesirable phenomena may be completely avoided by fixing a tube containing five milligrammes of radium bromide on the microtome knife in close proximity to the place where the paraffin-wax ribbon is forming. The breaking up of sections and consequent loss of continuity in the seriation may be thus avoided, the radiations from the radium discharging the electrification of the paraffin sections by ionising the air in their neighbourhood. This very ingenious device may probably be applied with equally satisfactory results in other instances where the cause of the trouble—namely, the electrification of sections or thin shavings—is the same.

THE CARE OF FEMALE INEBRIATES.

IN the *Standard* of July 1st there is a letter on the subject of female inebriates by Sir Alfred J. Reynolds, Sheriff of the City of London, which we are sure will be read with satisfaction by all right-thinking people. In it he announces that the London County Council has made ample arrangements for the admission of all classes of females committed within the metropolitan area (exclusive of the City) into inebriate reformatories certified under the Inebriates Act of 1898. All London cases can now therefore be committed without restriction as to age, condition, health, character, or religion. Sir Alfred Reynolds points out that during the year which ended on March 31st, to say nothing of the vast number of cases disposed of by fines, as many as 8256 women were committed by London magistrates to Holloway Prison for drunkenness and disorderly conduct alone Of these 580 had been three or more times convicted within the 12 months next preceding their last offence, while 4953 or 60 per cent of this number, had previous convictions for like offences The London County Council is to be congratulated upon having by its action facilitated the working of the Inebriates Act and it is hoped that not only will the expense to the public caused by this class of offenders against the social order be lessened but that much good in many other ways may accrue

---

The Marquis of Londonderry, President of the Board of Education has consented to receive on Monday next *July 11th at the Privy Council Office a deputation* of members of the medical profession who will present to him a petition in favour of the compulsory teaching of hygiene and temperance in public elementary schools The petition bears the signatures of 14 718 members of the medical profession

---

The Wightman lecture of the Society for the Study of Disease in Children will be delivered by Mr R Clement Lucas at the Victoria Hall Hotel Cecil London on Friday July 15th at 6 30 P M The title of the lecture is 'The Hereditary Bias and Early Environment in their Relation to the Diseases and Defects of Children The lecture is open to all members of the medical profession

THE VISIT OF THE KING AND QUEEN TO ST BARTHOLOMEW'S HOSPITAL

The laying of the foundation stone of the new building of St Bartholomew s Hospital by His Majesty the King took place on July 6th The King and Queen on arriving at the hospital were received in an ante room adjacent to an enormous marquee holding over 3000 invited guests Their Majesties were greeted by the Prince of Wales President of the hospital and Dr S Gee the senior physician to the hospital and Mr John Langton the senior surgeon were presented to the King The Royal guests were then conducted to the marquee where prayers having been read by the Bishop of London the Prince of Wales presented an address to the King and Queen which he read distinctly and loudly so that it could be easily heard by all in that vast assembly He referred to the foundation of the hospital in the year 1123 and commented on the record of the hospital since the year 1547 At the present day he said that St Bartholomew s Hospital contained 740 beds inclusive of 70 in its country branch at Swanley During the last 50 years the hospital had given gratuitous relief to more than *7 000 000* of the sick poor The students working daily within

fame of their alma mater all over the world The rapid

ice during recent years had com

ng on the advice of their eminent

late the entire rebuilding of the hospital as funds became available They had issued an appeal to the public to *enable them* to carry out the rebuilding referred to To the City of London and its wealthy citizens that appeal ought to come home with peculiar force for the hospital in its present development was in great measure the creation of the inhabitants of what had been termed 'the wealthiest square mile in the world St Bartholomew s Hospital had not asked for help for more than 150 years and the governors trusted that the presence of their Majesties that day might *be regarded by the public as showing their Majesties desire* that the rebuilding of that great and ancient institution might not be impeded and crippled for lack of funds

To this address the King returned the following reply 'The Queen and I have great pleasure in being present to-day to lay the foundation stone of the new building of this famous hospital and we thank you heartily for the loyal address which our dear son as President has presented on behalf of the governing body You have reminded us of the antiquity of this foundation and of the favour shown to it by so many of our Royal predecessors I recollect the lively satisfaction which I felt in holding the presidency of this hospital for so many years and I shall continue to take the deepest personal interest in its work and fortunes We are happy to see that those who are responsible for carrying on the excellent work have shown by their scheme for rebuilding the hospital their intention that the future of St Bartholomew s shall not be unworthy of its fine traditions in the past The names of the famous men educated here prove that an institution of this kind is not merely a refuge for the suffering but that it is also a school for the advancement of the science and practice of medicine and in this way the influence of this and other great hospitals of this country extends beyond merely local limits to foreign countries and the colonies and dependencies of our Empire We confidently believe that our subjects and especially the citizens of London will not fail to show interest in the progress of the scheme for rebuilding the hospital nor allow the efficiency of the undertaking to be hindered by want of the necessary funds

The Treasurer Sir **Trevor Lawrence** then formally asked the King to be pleased to lay the foundation stone and on the Royal assent being given the architect Mr E B I Anson was presented by the Treasurer and submitted to the King plans of the building proposed to be erected and then handed to His Majesty the trowel and mallet with which the King performed the ceremony of laying the foundation stone

The **Treasurer** then approached the Queen and asked if it was *her pleasure to receive her* charge as a Governor of the Hospital Her Majesty being the first lady elected a Governor as well as the first donor to the building fund The Queen having assented the charge was read by the Clerk of the Hospital Mr W H Cross in accordance with ancient custom and was as follows —

> Your Majesty having been elected and chosen a Governor of St.

The Treasurer then presented to Her Majesty a copy of the governor s charge and a governor s staff in miniature after which Madame Albani assisted by Miss Catherine Jones and other talented singers gave a well applauded rendering of Sir Edward Elgar s arrangement of God Save the King The royal party then *departed passing on their* return journey through the great quadrangle of the hospital amid the acclamations of many of the patients whose beds had been placed in the open air The King as he was leaving was pleased to announce that he would contribute towards the building fund the sum of £1000

In the special appeal now issued by the governor of St Bartholomew s Hospital the necessity is explained of the need the hospital labours under of rebuilding the institution in accordance *with modern requirements* The most pressing necessity of the time is the construction at a cost of upwards of £100 000 of new out patients casualty and special departments the foundation stone of which has just been laid by His Majesty the King This building will contain the out patients and casualty departments the special departments the resident medical officers quarters

resident medical officers quarters will be on the Giltspur-street frontage, where also there will be a common room and luncheon room for the students In the rear of the resident medical officers quarters there will be a large waiting hall for out patients and casualty patients Surrounding this waiting hall there will be 20 medical and surgical consulting rooms Rooms will also be provided for the reception and treatment of accident and emergency cases The dispensary will be in the rear of the waiting hall The hospital kitchen will be on the second floor over the dispensary The upper floors over the waiting hall will contain rooms for the treatment of surgical and medical out patients and the following special departments diseases of women, ophthalmic, diseases of the skin, aural, diseases of the throat, orthopædic, dental, and electric. Rooms containing ten beds will be provided in the building for the reception of patients who remain only a few hours in the hospital. Ample means of exit in case of fire or other emergencies will be provided and the building will be constructed with fire-resisting materials and fitted with the most approved sanitary and other appliances.

ARMY MEDICAL DEPARTMENT REPORT FOR 1902.[1]

THE nation and the Government are confronted at the present moment with a most comprehensive and difficult problem. It is how consistently with sound economy to get an army that shall be efficient and at the same time suited to the needs of the country and the empire. That is the task on which Mr. Arnold-Forster and the Government are at present engaged and the War Minister apparently does not despair of being able to accomplish it. At first sight the new volume of Army Medical Reports just issued would seem to have no direct and practical bearing on this problem, but a very little consideration will soon dispel that idea. To begin with it is as impossible to have an army without recruits as to have a river without water and that section of the report devoted to the recruiting of the army is calculated to arrest attention. It tells us that the total number of recruits rejected in 1902, inclusive of those who were discharged as unfit for service within three months of enlistment, was equal to a ratio of 325·42 per 1000 of those who presented themselves. Whether that portion of the population from which army recruits are mainly drawn can or cannot be considered as affording any criterion of the health and physique of the general population the figures nevertheless show the existence of conditions in our midst which point to want of proper food, good air, and wholesome surroundings, and fully justify the inquiries that are taking place. Moreover, it is a platitude to say that as far as our army is concerned health and physical efficiency go together and that these depend upon hygienic conditions the provision of which usually spells money.

Turning, however, to the more immediate subject of the report itself we select the following points from the excellent preliminary statement which in the course of the first few pages summarises the health of the troops at home and abroad. The average strength of the European troops in 1902, exclusive of the troops employed in South Africa during the period Jan. 1st to May 31st, was 254,357 warrant officers, non-commissioned officers, and men. The total number of admissions to hospital was 191,250 and the total deaths were 2152. The admissions represent a ratio of 751·9 per 1000 of the strength; the deaths one of 7·52 per 1000 on a strength of 286,026, which includes detached men not shown in the returns received. Amongst the troops serving in the United Kingdom the admission, mortality, and constantly sick rates were lower than in 1901. There were 114 admissions for, and 35 deaths from, enteric fever, which shows a fractional decrease in both the admission and mortality rates as compared with 1901 and is practically the same as the average rate. At Gibraltar the admission and constantly sick rates were lower but the mortality was somewhat higher than in 1901. In the Malta command, which included Crete, there was a decrease in the admission, mortality, and constantly sick rates. The admission and mortality rates for enteric fever were lower than in 1900 and considerably below the average rate. Malarial fever was again very prevalent in Crete, although the admission rate for the command was lower than in the previous year. In Canada the health of the troops was good, there being a decrease in the admission, mortality, and constantly sick rates. In Bermuda there was a serious epidemic outbreak of enteric fever and as the civil population also suffered to a large extent a commission was convened to inquire into the origin and spread of the disease. The opinion was that the enteric fever was of South African origin, brought to the colony by Boer prisoners of war. In Western Africa malarial fevers, though not so prevalent as in previous years, furnished the majority of the admissions. In Mauritius the admission, constantly sick, and death rates were higher than in 1901. Plague continued throughout the year amongst the civil population, no case occurring among the troops. Malarial fevers were prevalent, but there was a decrease in the admission rate as compared with 1901. In Ceylon the health of the troops was satisfactory. There was a slight increase in the ratio for venereal diseases as compared with the previous year. There was also an increase in the admission rate for enteric fever.

No case occurred amongst the troops at Diyatalawa, notwithstanding that the disease was more or less prevalent in the adjacent Boer camp throughout the year. In China the admission, mortality, and constantly sick rates were higher than in 1901. Malarial fevers showed a large increase as compared with the previous year. An epidemic of dengue which first attacked the native population and afterwards spread to the European community occurred during the summer and autumn of the year. The disease was of a severe type and was the cause of a large number of admissions among the troops as well as amongst the women and children. Plague was again epidemic and there were also a large number of cases of cholera among the civil population, but among the troops only a single admission under each of these diseases occurred. In India there were a decrease in the admission, constantly sick, and invaliding ratios and an increase in the mortality rate. The chief causes of sickness as usual were malarial fevers and venereal diseases, which together caused 49·63 per cent. of the admissions for all diseases. Malarial fevers and dysentery were less prevalent than in 1901 while venereal diseases and enteric fever both showed an increase as compared with the previous year. As regards enteric fever it is noted that the satisfactory steady annual decrease which had been taking place since 1899 has not been maintained and there has also been an increased death-rate from the disease. The increase in the number of admissions, occurring as they do for the most part in young soldiers during their first year's service in India, is attributed to the arrival of large drafts from home and reliefs from active service in South Africa. The chief points observed during 1902 in connexion with the causation of enteric fever in India are discussed at length. During the year three fatal cases of cholera occurred and there were also four admissions for plague, one of which terminated fatally. In Egypt the admission, death, and constantly sick rates were lower than in 1901 and were also lower than the rates for the decennial period. The ratio of admission for enteric fever was fractionally higher than in the previous year and that for venereal diseases was lower. Cholera broke out about the middle of July in a village in Upper Egypt and spread to Cairo and Alexandria where it became epidemic among the civil population. Three cases occurred amongst the troops at Cairo with fatal results and there were two fatal cases amongst officers at Alexandria. The last case in Cairo occurred in November, but the disease still remained in Alexandria at the end of the year. Khartum was again used during a portion of the year as a station for British troops.

Some new charts for the various commands occupied by British troops in 1902 and four new abstracts have been prepared and added to the present volume. These besides being new strike us as an instructive and useful feature, the abstracts being calculated to carry out the intention of their compilers—namely, to facilitate the making of statistical comparisons and to unify the statistical details for the whole army at home and abroad.

We wish to call special attention to the extracts (p. 136 *et seq.*) from an exhaustive and admirable report of Lieutenant-Colonel W. G. Macpherson, C.M.G., R.A.M.C., which has been circulated as an official publication, on the sanitary conditions in South Africa and to the information and valuable remarks embodied in the report on the health of the European troops serving in India in regard to the causation of enteric fever in that country (pp. 201 and 205 *et seq.*) and to those on venereal disease (*vide* p. 233 *et seq.*).

At the end of the section of the Army Medical Report dealing with the health of the troops on board ship we find it noted that, according to returns received at headquarters, the number of invalids from the South African Field Force who returned to England during the year was 16 004 1 14 deaths occurred during the voyage home of the South African invalids are reserved records of the campaign

MR CHAMBERLAIN AND PREVENTIVE MEDICINE

THE Royal Institute of Public Health gave a banquet on June 30th at the Criterion Restaurant London in honour of the Right Hon Joseph Chamberlain and in recognition of his services to preventive and tropical medicine whilst filling the office of Colonial Secretary from 1895 to 1903 The chair was taken by Dr W R Smith President of the Institute and amongst those present were the Right Hon A J Balfour the Duke of Northumberland the Duke of Marlborough, the Duke of Abercorn the Earl of Onslow Lord Strathcona, Lord Iveagh Mr A Lyttelton Sir Joseph Fayrer, Sir Patrick Manson, Surgeon General Sir Francis Lovell Sir William Broadbent Major Ronald Ross Professor T Clifford Allbutt, Mr J Cantlie Lieutenant Colonel R H Firth, R A M C Professor R Boyce Professor C S Sherrington, Mr W M Haffkine, and Dr J Mitchell Bruce

Before the usual loyal toasts were honoured the Honorary Fellowship of the Royal Institute of Public Health was bestowed upon Mr Balfour Lord Iveagh, and Mr Chamberlain

Dr SMITH, in proposing the health of the guest of the evening Mr Chamberlain said that they were deeply indebted to him for the great progress which it had been possible to make in various branches of research He then alluded to the services which Mr Chamberlain had rendered in regard to preventive medicine and when the speaker explained how through Mr Chamberlain s agency the London School of Tropical Medicine was founded the audience greeted the remark with prolonged cheering

When Mr CHAMBERLAIN rose to reply he was received with such an outburst of applause that he had to wait some considerable time before he commenced his speech in the course of which he said that as Secretary of State for the Colonies there was brought home to him, as there must be brought home to everyone who filled that position, the importance of caring for the health of those who were doing the work of the Empire across the seas He took advantage of the opportunities which his office gave and was able to secure some tangible expression of the interest which was universally felt in preventive medicine so as to give effect to the work of such institutions as the Royal Institute of Public Health He accepted the honour which was done him that evening because a gathering of the kind they saw before them, bringing together the experts in medical science and the statesmen and legislators who could give effect to their con but good cou nportance nterested has been made in medicine said that he did not know ent which had made Lord Lister s name a household word throughout the world and gained for him the gratitude of the human race was to be considered a triumph of surgery or of medicine but he did know that medical research assisted by surgical science, had in the last few years thrown a flood of light on the origin of disease and that certainly was the first step to the cure of disease He could not tell whether it would be possible greatly to extend the three score years and ten which was the Psalmist s limit of normal human life, but he hoped that their descendants might pass through their earthly course with less suffering and more vigour than their predecessors While they looked with confidence to the further results of curative medicine, he thought all would agree that preventive medicine was better still The importance of securing healthy conditions of life was recognised by everybody who cared for the welfare of his fellow creatures Without sanitary reform social reform was an empty phrase, preventable disease at that moment was a great agent for filling the workhouses raising the taxes, and weakening the fibre of the people In peace preventable disease was of the utmost importance in war it destroyed more soldiers than the bullets of the enemy, and meanwhile ure was lessened in efficiency which its agents were con the efforts of men like Sir Patrick Manson, Professor Ross Professor Haffkine and the others who had been devoting their time to tropical medicine and to research and to the causes of tropical diseases and their remedies that his attention and warmest sympathy were chiefly directed The work of the century was the consolidation of the Empire and wherever the British rule was established there they would find the Government officials dealing with every conceivable problem of education of trade of health and of the development of the countries given to their charge Those men were the great assets of the Empire, they must prize them and value them and do everything to keep them in the vigour of life and it was for that reason Mr Chamberlain said that he attached so much importance t studies and to the researches wl of time would make those tropic each in their turn the white man s grave places where white men could live in comfort Mr Chamberlain concluded by saying that that was the reason why one of those almost unknown students working in laboratories in London Liverpool and elsewhere might be doing more good for the Empire than any state man had been able to do however high his position

Mr BALFOUR in responding to the toast of Preventive Medicine and the State proposed by the Duke of NORTHUMBERLAND said that preventive medicine was concerned with the fact that the urban population was increasing relatively to the rural population which raised the problem whether the result would be some falling off from the ancestral vigour of the race The internal problem for preventive medicine was therefore to see that deterioration did not occur in the great accumulations of our population in the ever growing centres But there was the external problem for preventive medicine as to how they were going to develop the great tropical regions under British superintendence if the best of the men who were sent out were cut off in the prime of their existence The blood tribute hitherto exacted from the British race in the great tropical r impossible unless turn those great turned the great tropical colonies into places where the white man could live in reasonable health and comfort there would be added directly and indirectly incalculable gains to the prosperity of the British Empire

Mr CANTLIE the honorary secretary of the Institute in a witty speech proposed the toast of The Guests ' which was acknowledged by Lord ONSLOW

The Duke of MARLBOROUGH then proposed ' The Royal Institute of Public Health, which was replied to by Dr SMITH

THE MIDWIVES ACT, 1902.

THE members of the Central Midwives Board met on June 30th at 6 Suffolk street London S W , Dr F H CHAMPNEYS being in the chair

Under Section 3 of the Midwives Act it is laid down that one of the duties and powers of the Central Midwives Board is to appoint examiners and this matter came under the notice of the Board appearing on the agenda paper as the first item of business after the reading of the minutes of the last meeting

Dr C J CULLINGWORTH opened the discussion by proposing that a list of examiners both for London and the provinces should be prepared by the Central Midwives Board from those who were willing to serve and to act when required by the Board

Dr J WARD COUSINS at once raised the important point that by merely putting the words a list of examiners no restriction was placed upon the choice of examiners Dr Cousins did not waste any time but in a very few words made out a good case for the view that the examiners should be registered medical practitioners He urged that the Central Midwives Board ought to work so as to gain the confidence of the medical profession because it was through practitioners that the Board would have to work It was necessary therefore to secure the support of profession and to do that the Board must examiners must be qualified practitioners. There was also the further consideration that the subjects of the examination required medical men as examiners. Dr. Cousins therefore moved as an amendment—

> That the wording of the clause should be "a list of examiners who shall be registered medical practitioners."

Mr. E. PARKER YOUNG supported the amendment and said that it was a retrograde movement to suggest that the examiners might be other than registered medical practitioners. He very clearly brought out the weighty argument that the public demanded that the examiners under the Midwives Act should be highly qualified medical men commanding the esteem and confidence of the profession.

Miss WILSON took quite the opposite view. She said it was not a retrograde movement and her reasons were that a matron or a midwife would be a useful addition to the Board of Examiners because very few medical men undertook to teach details of nursing.

Dr. CULLINGWORTH thought that the examiners chosen would be for some time to come qualified medical men but considered that the Board should be left free to appoint, if it thought right, a trained midwife or matron as an examiner. He said he would not lend himself to the appointment of midwives as examiners straight away or without consideration but he contended that the Board ought to have the liberty to do so if it so wished.

The amendment restricting the examiners to qualified medical practitioners was, however, lost on being put to the vote and the Central Midwives Board is therefore now free to appoint anyone whom it chooses to select to the post of examiner. It is worth putting on record that Dr. W. J. SINCLAIR before recording his vote in favour of the amendment warned the Board that its duty was to make it clear to the medical profession and to all who wished to enter for the examinations that those examinations would be carried out by duly qualified medical practitioners, otherwise what was to prevent a highly-gifted chambermaid from being made an examiner? Dr. COUSINS also succeeded in sounding a note of warning before he gave his vote in favour of the amendment and no one at the Board seemed anxious or ready to answer his question as to how any woman trained or taught under the flimsy rules and regulations of the Midwives Act could possibly be considered properly qualified to undertake the duties of an examiner. There are few medical men who will not agree with Dr. Cousins that it would have given the profession great satisfaction if the Board had accepted the amendment and restricted the choice of examiners to properly qualified registered medical practitioners.

The first examination under the Midwives Act is to be held in May, 1905, and after that the examinations will take place twice a year in London and the provinces simultaneously on the same papers, or more often if necessary. The provincial centres are Bristol, Manchester, and Newcastle-on-Tyne. The arrangements and regulations referred to in the preceding lines were not arrived at until after a long and wearisome discussion in which the same arguments were often repeated involving much waste of time. Some members of the Board should remember that the mere repetition of an argument or opinion does not tend to strengthen it but if anything constant iteration may weaken its effect.

Among the directions to examiners the Board agreed to include one that directs the examination to consist of not fewer than six questions, the time allowed for answering to be three hours. The examinations are to consist of a written and an oral part and are to be conducted by not less than two examiners. In connexion with the question of the examination Miss R. PAGET asked if there should not be some laxity at first. "Surely," she said, "for the first examination you will not be too strict." Dr. CHAMPNEYS explained that it was necessary to start with a proper standard to which Miss PAGET replied, "Surely medical examinations began gently." Later this speaker further urged that laxity in the examinations was to be considered because the country was in need of midwives, but as Dr. SINCLAIR very rightly pointed out that amounted to an argument of pity, the practical effect of which would be that the country would be supplied with an inferior article.

After consideration of applications for certificates the names of 829 women were passed under Section 2 of the Act and ordered for entry on the roll, the total number enrolled being 6159.

Looking Back.

FROM

THE LANCET, *SATURDAY,* JULY 8, 1826.

Diseases of the Pancreas.[1]

Little need be said upon this subject because it is hardly possible to discover the existence of disease in this organ during life, so as to distinguish it with certainty from that of the neighbouring parts. That the pancreas is liable to inflammation, and that in various degrees, may be easily inferred from analogy. Such a state might be suspected from the occurrence of deep-seated pain in the epigastric region, increased upon pressure. If the organ were enlarged or hardened by the disease, it might perhaps be felt upon examination, at least in emaciated subjects. It would be very likely to disorder the functions of the stomach.

The accuracy of our diagnosis in such a case, would be of no great importance, as it would require only the common treatment of inflammation; which it is unnecessary therefore to again particularize.

FOREIGN DEPARTMENT.

THERAPEUTICS.

On the use of Belladonna as a Prophylactic in Scarlatina. (Rust's Magazin, fur die gesammte Heilkunde, xx vol. p. 182).

SEVERAL notices have been published of late, particularly in German journals, regarding the prophylactic virtues of the extract of belladonna in epidemics of scarlatina. The following experiments made at the orphan hospital of Langendorf in Prussia, by Dr. Randhahn, physikus of the place, is one of the strongest facts in favour of the alleged property. In one of the apartments of the hospital two children were attacked by scarlet fever, in February 1825, and 160 others were exposed to it. A solution of three grains of the extract of belladonna in an ounce of a vinous infusion of cinnamon, was given to each in small doses, during the whole month of February. Up to the 21st of April, when the report was made by the physician, not a single case had occurred among them, and even two who lived in the same chamber with those affected did not suffer.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on June 30th, Sir WILLIAM S. CHURCH, Bart., K.C.B., the President, being in the chair.

The PRESIDENT announced the following nominations to lectureships for 1905: Dr. W. C. Bosanquet as Goulstonian lecturer; Dr. W. H. Allchin as Lumleian lecturer; Dr. Norman Moore as FitzPatrick lecturer; Dr. Leonard E. Hill as Oliver-Sharpey lecturer; and Dr. W. H. R. Rivers as Croonian lecturer.

Licences to practise were granted to two candidates (Mr. Eric Gardner and Mr. George Alick Soltau).

Communications were received from: 1. The General Medical Council, containing resolutions of the Council with regard to preliminary scientific education and examination and rules with regard to diplomas in public health, both adopted in May last. This was referred to the committee of management. 2. The secretary of the Royal College of Surgeons of England, reporting certain proceedings of the Council on May 12th. This was received and entered on the minutes. 3. The same, reporting certain proceedings of the Council on June 9th, communicating also a report of a special committee on the question of instituting a diploma in tropical medicine and inviting this College to a conference on the subject. This was agreed to, the nomination of representatives being left to the President.

Reports were also received from the laboratories committee, the committee of management, and from the examiners for the Licence on the results of the examinations in April last.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8643 births and 3953 deaths were registered during the week ending July 2nd. The annual rate of mortality in these towns, which had been 14·2, 13·8, and 13·2 per 1000 in the three preceding weeks, increased again last week to 13·5 per 1000. In London the death-rate was 12·9 per 1000, while it averaged 13·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 5·1 in Tottenham, 6·1 in Leyton, 7·0 in Handsworth (Staffs.) and in King's Norton, 7·1 in Hornsey, 8·2 in Reading, 8·5 in East Ham, 8·6 in Northampton, and 8·7 in Newport (Mon.); while the highest rates were 17·7 in Liverpool and in Bootle, 18·1 in Hull, 19·0 in Manchester and in Newcastle-on-Tyne, 20·0 in Great Yarmouth, 20·3 in Huddersfield, 21·6 in Wigan, and 22·8 in Hanley. The 3953 deaths in these towns last week included 455 which were referred to the principal infectious diseases, against 492, 487, and 444 in the three preceding weeks; of these 455 deaths, 180 resulted from measles, 102 from whooping-cough, 82 from diarrhœa, 44 from diphtheria, 25 from scarlet fever, 16 from "fever" (principally enteric), and six from small-pox. No death from any of these diseases was registered last week in Willesden, Hastings, Southampton, Reading, Handsworth (Staffs.), Aston Manor, Bury, Rotherham, Tynemouth, or Newport (Mon.); while the highest death-[illegible]d in [illegible]otle, [illegible], and Rhondda. The [illegible]om measles occurred in [illegible] Liverpool, Bootle, Manche[illegible] Hull, and Rhondda; from [illegible] in Bootle; from diphtheria in Hanley, West Hartlepool, and Rhondda; and from whooping-cough in Great Yarmouth, Grimsby, and York. The mortality from "fever" and from diarrhœa showed no marked excess in any of the large towns. Of the six fatal cases of small-pox registered in these towns last week two belonged to Gateshead, two to Newcastle-on-Tyne, one to London, and one to Oldham. The number of small-pox patients under treatment in the Metropolitan Asylums Hospitals, which had been 95, 80, and 83 at the end of the three preceding weeks, had declined again to 74 at the end of last week; 10 new cases were admitted during the week, against 21, seven, and 16 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday last, July 2nd, was 1631, against 1647, 1630, and 1629 on the three preceding Saturdays; 254 new cases were admitted during the week, against 193, 206, and 199 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 157, 142, and 141 in the three preceding weeks, rose again last week to 146, but were 19 below the number in the corresponding period of last year. The causes of 35, or 0·9 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Leeds, Hull, Newcastle-on-Tyne, and in 54 other smaller towns; while the largest proportions of uncertified deaths were registered in Liverpool, Bootle, St. Helens, Manchester, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16·2, 17·0, and 15·9 per 1000 in the three preceding weeks, rose again to 16·3 per 1000 during the week ending July 2nd, and was 2·8 per 1000 in excess of the mean [illegible] large English t[illegible] ranged from 1[illegible] Aberdeen and [illegible]ch were referred to whooping-cough, [illegible] measles, four to scarlet fever, three [illegible] "fever," and two to small-pox. In all [illegible]m these [illegible] 66, and [illegible] weeks. These [illegible] deaths were [illegible] 2·3 per 1000, which was 0·7 per [illegible] last week from the same diseas[illegible] towns. The fatal cases of [illegible] been 21 and 27 in the two preceding weeks, further rose last week to 31, of which 14 were registered in Glasgow, eight in Edinburgh, four in Dundee, and four in Paisley. The deaths from diarrhœa, which had been 24, 20, and 22 in the three preceding weeks, declined again to 18 last week, and included eight in Glasgow, four in Aberdeen, and two in Dundee. The fatal cases of measles, which had been 16, 14, and 12 in the three preceding weeks, rose again last week to 14, of which five occurred in Edinburgh, four in Glasgow, two in Dundee, and two in Aberdeen. The deaths from scarlet fever, which had been two in each of the two preceding weeks, increased last week to four, all which were registered in Glasgow. The fatal cases of "fever," which had been two and four in the two preceding weeks, declined again to three last week and included two in Dundee. The deaths from small-pox, which had been three, three, and one in the preceding weeks, rose again last week to two, both of which belonged to Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 68, 93, and 64 in the three preceding weeks, rose again last week to 80 but were six below the number in the corresponding period of last year. The causes of 26, or nearly 5 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 18·3, 21·7, and 19·5 per 1000 in the three preceding weeks, further declined to 16·5 per 1000 during the week ending July 2nd. During the 13 weeks of the quarter ending on that date the death-rate has averaged 21·7 per 1000, the rates during the same period being 14·8 in London and 17·2 in Edinburgh. The 120 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 22 from the number in the preceding week and included seven which were referred to the principal infectious diseases, against four, six, and three in the three preceding weeks; of these, two resulted from measles, two from scarlet fever, one from diphtheria, one from whooping-cough, and one from diarrhœa, but none from either small-pox, or "fever." These seven deaths were equal to an annual rate of 1·0 per 1000, the death-rates last week from the principal infectious diseases being 1·5 in London and 2·4 in Edinburgh. The 120 deaths in Dublin last week included 21 among children under one year of age and 29 among persons aged 60 years and upwards; the deaths of infants were slightly in excess of the number in the preceding week, while those of elderly persons showed a marked decline. Three inquest cases and three deaths from violence were registered; and 53, or more than two-fifths, of the deaths occurred in public institutions. The causes of four, or more than 3 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified: Staff Surgeon: H. Huskinson to the *Vivid* for Pembroke Dockyard (dated June 22nd). Surgeon: A. T. Wysard to the *Albion* as Interpreter in German.

ROYAL ARMY MEDICAL CORPS.

Lieutenant G. F. Rugg, Lieutenant J. Fairbairn, Lieutenant J. A. Turnbull, Lieutenant R. B. Hole, Lieutenant M. F. Grant, Lieutenant H. Harding, and Lieutenant A. A. Meaden proceed to Woolwich for duty

Major J. R. Mallins, on arrival home from Halifax, N.S., has been posted to Portsmouth for duty. Lieutenant F. M. M. Ommanney has been appointed medical officer with the 6th (Somaliland) Battalion Royal African Rifles.

Lieutenant-Colonel A. P. O'Connor, C.B., now at Gibraltar, has been appointed Principal Medical Officer, 3rd Division, First Army Corps.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major F. K. Pigott to be Surgeon-Lieutenant-Colonel (dated June 21st, 1904). Brigade-Surgeon-Lieutenant-Colonel W. P. Whitcombe, Worcester and Warwick Volunteer Infantry Brigade, to be Surgeon-Major (dated July 6th, 1904). Surgeon-Lieutenant L. A. Avery, Suffolk Imperial Yeomanry, to be Surgeon-Lieutenant (dated July 6th, 1904). Surgeon-Major E. J. Hunter to be Surgeon-Lieutenant-Colonel (dated June 14th, 1904).

ROYAL ARMY MEDICAL CORPS (MILITIA).

Captain J. E. O'Connor resigns his commission (dated July 2nd, 1904). Supernumerary Lieutenant S. G. McAllum to be Captain (dated June 4th, 1904).

IMPERIAL YEOMANRY.

South of Ireland: The appointment of Surgeon-Lieutenant F. F. MacCabe bears date July 30th, 1903.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the Highland Light Infantry: Surgeon-Captain W. Sandeman to be Surgeon-Major (dated July 2nd, 1904).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Aberdeen Company: Major J. MacK. Booth resigns his commission with permission to retain his rank and to wear the prescribed uniform (dated July 2nd, 1904).

THE ARMY APPEAL BOARD.

Mr. Arnold-Forster has informed Captain Norton that after every medical examination of candidates for commissions in the army numerous representations are made on behalf of those rejected, supported by medical certificates. It was therefore considered expedient to institute an Appeal Board the decision of which should be final. The number of candidates examined since its inception is 234 and the cost of public money spent in fees has been £982 16*s*. The Army Council does not propose to abolish the Board at present but the matter is one of importance and is receiving consideration.

THE WAR IN THE FAR EAST.

Owing to the advent of torrential rains, the topographical difficulties of the country, which have been thereby greatly increased, and the possible insufficiency of land transport there has been a comparative lull in the military operations in the Far East. There has consequently been but little to record during the past week, the latest news being the reported repulse of the Russian attack on Mo-tien-ling Pass. From the side of the sea we learn that a portion of the Vladivostock fleet made an unimportant raid outside and again escaped Admiral Kanimura's squadron. As regards Port Arthur, its land investment seems to be complete but whether its capture by assault will be soon attempted or not we do not yet know for certain. The general line of the Japanese army may be described as extending diagonally from south-west to north-east along the line of railway to Mukden. The report of the Japanese having abandoned the Taling Pass proves to be unfounded. A Reuter's telegram emanating from General Kuropatkin's headquarters states that the Japanese have at length occupied the Mo-tien-ling Pass without opposition, much to the surprise of the foreign attachés who were amazed at seeing three formidable lines of earthworks abandoned without even a show of resistance. This abandonment was, as suggested, no doubt due to fears on the part of the Russians for their line of retreat. The dominating part which the Japanese artillery has played throughout the war and the skill with which it has been handled have been freely acknowledged by the Russians. Considering the heavy rains and the sodden condition of the soil the unfortunate soldiers in the "field" on both sides have been subjected to considerable exposure and hardship which must, we should think, be telling gravely upon their health and efficiency; of this we hear but little, however, at present. We learn from Russian sources that much cholera prevails among the Japanese troops but of the truth of this we are somewhat sceptical. That the amount of inefficiency attributable to sickness among the troops in the field is considerable cannot be doubted and it is most probably largely in excess of the loss occasioned by wounds in fighting. It will be remembered that the Russians recently brought some serious charges of cruelty against the Japanese which the latter have since not only indignantly repudiated but have advanced counter-charges of the treatment which their wounded had met with at the hands of the Russians, in spite of which the Russian wounded picked up by the Japanese had, they allege, been kindly treated. Criminations and recriminations of this nature are usually found to be barren of any good purpose; when the facts are carefully investigated they generally turn out to have been either exceptional, exaggerated, or even without any foundation. Those of our readers who are interested in the organisation of the Japanese army and its medical corps should consult an article on "Japan at War" by Colonel E. Emerson in the *Contemporary Review* for the present month for a brief account thereof, and as regards the medical services in the Russian army (peace) we may direct attention to a paper by Lieutenant-Colonel J. Hickman, R.A.M.C. (retired pay), in the *Journal of the Royal Army Medical Corps* for July.

The *Sphere* of July 2nd contains some excellent reproductions of photographs relating to medical matters in connexion with the war. There is a panoramic view of the hospital court-yard crowded with Japanese wounded at Antung immediately after the Yalu battle, stretcher-bearers carrying a wounded Russian, and a representation of a Japanese field hospital with operation table, operator, and assistants. Portraits of the medical men and nurses of the Russian Society of St. George are also given together with an illustration of a Russian hospital equipment on the shores of Lake Baikal.

In the wagon-building shops of the Kasan Railway the fitting up of the wagons for the circulating laboratory and room for live animals, such as guinea-pigs, is proceeding actively. Accommodation for the staff and disinfecting rooms is afforded in separate wagons. The specific object of this train is to combat infectious disease. In the same workshop there is in course of preparation a train to carry ice-making machinery and ice safes, with the necessary apparatus and accessories, all to go forward to the seat of war when ready, which will be in a few days. The *Novosti* announces that at the military medical factory the fitting up of the interior of the chemico-bacteriological laboratory is almost finished. The laboratory will be devoted to testing muslin, wool, textiles, and other materials entering into the preparation of antiseptic bandaging which the factory supplies to the whole army.

LEPER CAMPS IN RUSSIA.

The Military Medical Executive has undertaken the construction of a series of leper camps in the Don, Kouban, and Tver districts to deal with the disease in the respective localities.

Correspondence.

"Audi alteram partem."

THE APPEARANCE OF BACTERIA IN NORMAL ORGANS AND THE SIGNIFICANCE THEREOF.

To the Editors of THE LANCET.

SIRS,—That the blood of healthy animals possesses (1) marked bactericidal properties and (2) that the internal organs of healthy animals are free from living germs have long been cardinal tenets of modern bacteriology. These views owed their origin to the work and writings of Pasteur, Lister, Duclaux, and others. Still from the time of their first enunciation up to the present day doubts have ever and anon arisen as to the correctness of the latter conclusion and a long series of experiments and observations have been made by numerous investigators bearing upon this all important question. The last of these investigations appears in your columns for July 2nd, p. 21, in which the writer, Mr. H. de R. Morgan, details the results of careful work carried on in the Lister Institute upon the organs of different animals dealt with in ways which he fully describes. He considers himself entitled to come to the following conclusions "1 That normal organs do not contain pathogenic bacteria 2 That the presence of non pathogenic organisms in the cultures is probably due to accidental contamination He thinks, in fact that in spite of all the precautions taken common organisms from the air had 'fallen on the surface of the organs during some part of the manipulations

His experiments were made in consequence of a previous careful and elaborate investigation made by W W Ford[1] of Montreal, carried out in the laboratory of Professor Adami Ford came to the conclusion that at least 70 per cent of the internal organs of our ordinary domesticated animals contain bacteria which are capable of development provided a sufficient time be allowed to elapse between the removal of the organs and then final examination Ford felt positive that in his experiments, owing to the great care taken bacteria were not introduced from without by careless manipulation of instruments or media And the fact should not be lost sight of that many years ago a similar conclusion was arrived at by the present distinguished president of the Pathological Society of London Writing in 1878[2] Sir J Burdon Sanderson after detailing his own investigations conducted with every precaution, spoke as follows ' Under the conditions I have described to you it seems to me quite impossible to suppose

to the organ from the out

by the organ in its transit

o the brain could escape

destruction If therefore bacteria be found they or their germs *must have been there before the organ was plunged into the hot liquid*[3] The result of all the experiments whether with liver or kidneys was the same The soft red kernel of uncooked tissue at the middle of the organ always contained bacteria the vigorous development of which was indicated

and active movement

conclusive Seeing

obtained by other workers previous to 1878 it is not a little remarkable that Morgan should have been content to assume that mere surface contamination could have accounted for his numerous positive results Even if he had ignored or been unaware of these earlier investigations there was the statement of Ford before him that bacteria were found on microscopical examination in the interior of various of the organs dealt with

The experiments of Burdon Sanderson do not seem open to question The method employed by him of dropping the organs into superheated paraffin seems indeed likely to lead (as it did) to more uniform results than the method employed by Morgan and Ford The former says the organs were ' quickly passed through the flame of a Bunsen burner while the latter is rather more explicit and says that the organs were "cooked in the flame until the surface had been thoroughly scorched to a greyish brown colour Internal portions of the organs may have been at times too much cooked' by such a process and this may have led to the absence of organisms in a varying percentage of their experiments Where organs of some size are used another method employed by some experimenters is I think also thoroughly trustworthy for getting rid of all surface contamination and yet very simple I mean the dropping of the organs for a certain number of hours into a 2 per cent solution of chromic acid so that the acid may penetrate and colour the whole external portions of the organs for a depth of about one fourth of an inch After four hours or so the protected organ may be transferred to a closed sterilised vessel and submitted to incubating heat for a number of days varying according to the temperature employed Subsequently the red unstained tissue in the central parts of the organs will be found to swarm with bacteria

The fact that bacteria can thus be made to appear in swarms in normal organs has been thoroughly proved There is no more room for doubting it now than there was when Burdon Sanderson wrote in 1878 The question of *the interpretation of such results* is doubtless one of great difficulty to many and will never be solved till investigators are willing to look *all* the facts in the face with minds perfectly open and ready to draw the most warranted conclusions—irrespective of all antecedent notions It seems necessary to make so trite a statement because there is in the minds of most

bacteria cannot

based upon the

the consequent

they can arise by archebiosis The question of the *de novo* origin of bacteria by heterogenesis seems never to be seriously considered by bacteriologists They for the most part persistently ignore such a possibility

We find ourselves however in this position Bacteria have been shown to be capable of appearing in the organs of healthy animals notwithstanding all early beliefs to the contrary But unless we can conclude that bacteria must be capable of arising *de novo* in the cells of such organs after the death of the animal to which they belonged their discovery in such situations would be in flagrant contradiction with the two doctrines which I have referred to at the commencement of this letter as cardinal tenets of modern bacteriology Their presence would tend to stultify the doctrines and work of Lister and all the beneficent life giving results which have followed therefrom How ludicrous would be all the talk and work concerning the production of asepsis if all internal organs and tissues are *during life* permeated by germs of micro organisms Do not the modern results of the work of skilled surgeons in all civilised countries tend to show that no such permeation exists ? Organisms in abundance obtain entry to the alimentary tract and to the air passages but how are they to be disseminated to all the organs and tissues of the body if the blood is endowed with the bactericidal qualities which it is commonly said to possess ? The supposed existence of such an endowment would be shown to be an error if bacteria could be proved to exist *during life* in the organs of healthy animals as some would have us believe

The only other means (apart from the agency of blood vessels and lymphatics) of accounting for the dissemination of bacteria through the body is the supposition which was favoured in 1878 by Burdon Sanderson—namely that they are even in healthy animals capable of passing through the walls of the alimentary canal and thereafter wandering into this or that contiguous organ such as the spleen, the liver, or the kidney Apart from the fact that such a supposition (at the time supported by no independent evidence) is at variance with the more recent work of Opitz and Welch it in no way suffices to explain existing difficulties It is certain for instance that recognisable bacteria are not to be found in such organs of healthy animals immediately after death It is further known that when later they do appear they show themselves first as mere minute motionless particles which subsequently take on typical bacterial forms *But in the germ stage all these organisms are motionless* How can it be supposed therefore that such motionless germs can make their way not only through the intestinal canal but into this or that abdominal organ and even into all the individual cells of such an organ ? In proof that they may be so found I have shown[4] what occurs when a healthy sheep's kidney is treated in the manner I have indicated by soaking first in 2 per cent chromic acid and then transferred to a sterilised vessel at about 25° C for three or four days In such an organ every section revealed inside the area which had been affected by the chromic acid that almost every cell within the renal tubules was full of developing or actually developed bacteria The former appeared as mere cocci like particles which had taken the stain like the developed bacteria—both being situated in the midst of cell granules comparatively unstained (Photographs that are given of the sections show the distribution of the bacteria to be as above indicated)

Such facts seem incapable of receiving any rational explanation apart from the conclusion that the organisms found had arisen *de novo* after death in the previously healthy organs Their appearance within almost every epithelial cell of the kidney is just what might be expected if they had taken their origin there by heterogenesis What stands in the way of such a conclusion ? A preconception—nothing more On the other hand, apart from heterogenesis the presence of bacteria in such organs could only be accounted for by one or other of the two suppositions to which I have referred Either (1) by the self contradictory notion that

passing through the intestinal

us or that organ there to re

, or (2) by the admission that

[4] Studies in Heterogenesis 1904 pp 303-312

all that has been said concerning the bactericidal properties of the blood has been a false and mistaken notion. Either of these attempted explanations would, moreover, be equally at variance with the doctrines of Lister and the beneficent practice which he initiated. Such suppositions are, in fact, condemned by the life-saving results of his practice. Had either of the above attempted explanations of the fact that bacteria can be made to appear at will within the tissue elements of previously healthy organs been true—explanations, that is, which suppose that such organisms or their germs exist as such during life in the organs of healthy animals—then, as I have already indicated, the efforts to procure asepsis, as now practised by surgeons all over the civilised world, would be solemn but unreasoning mockeries and nothing else.—I am, Sirs, yours faithfully,

H. CHARLTON BASTIAN.

Manchester square, W., July 4th, 1904.

IN THE MATTER OF THE TAMWORTH TOWN COUNCIL.

To the Editors of THE LANCET.

SIRS,—My attention has just been drawn to some remarks you make in your issue of June 18th relative to the Tamworth town council and its medical officer's report. Perhaps you will permit me to say that your remarks show that the information you have received, and upon which you have based your remarks, is *absolutely incorrect* and *misleading*, and has no doubt been supplied to you from some "official" source with the view of using *your* weighty *opinion* to bolster up the official's cause. At the time I moved the resolution in the council—"That the medical officer's report be submitted to the chairman of the sanitary committee before being printed"—I had no wish, as I explained to the council at the time, to in any way *revise* or *alter* the report *and the medical officer has never been asked by the council or the mayor* to *omit* anything from his report. The chairman of the sanitary committee, I believe, did suggest some alteration in the manner or the language in which the doctor had expressed his views on some very minor matter but no attempt whatever was made, as you suggest, to get the doctor to alter or omit anything from his report that would in any way conceal anything from the Local Government Board or county council; in fact, the present Mayor of Tamworth and his friends on the council will be very glad if the medical officer of health will wake up a bit and send in his reports at the proper time and not three or four months after date and after repeated requests for the same from the authorities you quote; also they will be grateful to him if he will show up all the weak spots in the *sanitary state* of the town and not devote so much space in his reports to ornithological essays, &c. The present Mayor of Tamworth and his friends are [illegible] in their power to push on with a [illegible] reform, *including* an up-to-date system of sewerage and sewage disposal. Perhaps you will also permit me, too, to suggest to you the [illegible] ing that any information sent to [illegible] correct before you proceed to critic[illegible] the Tamworth town council or its [illegible] people know more about Tamworth's requirements than does the Editor of THE LANCET and also they know who are the most likely men to study their interests. They also know that if any apology is due to anyone it is due from the doctor to the sanitary committ[illegible] unnecessary manner in which [illegible] would like just to say that the r[illegible] support of the majority of the [illegible] in his praiseworthy efforts to rescue [illegible] the hands of the "officials" who for the [illegible] exercised, their ingenuity in looking after number one with the most baneful effect on the public spirit of the town. The present mayor, by his gr[illegible] strict economy, has been able [illegible] orough in three years from 8s. [illegible] 6s. 5*d*. without sacrificing [illegible] possible to [illegible] other greatly-needed measures of reform.

I am, Sirs, yours faithfully,

T. B. ALLKINS.

Hill Crest, Tamworth.

*** We received this letter last week too late for insertion. We publish it in spite of its futility. Our article, stated by Mr. Allkins with genial observance of the ordinary courtesies of life to be "absolutely incorrect and misleading," pointed out that it was well that the medical officer of health of Tamworth had obeyed the law and submitted his report to the Local Government Board instead of allowing it to be supervised by the Tamworth town council. In consecutive sentences Mr. Allkins says (1) that he moved for the medical officer's report to be submitted to the chairman of the sanitary committee before being printed, having no wish that the report should be revised and altered; and (2) that the chairman of the sanitary committee suggested alterations. It seems to us that those alterations would probably have been made if the wrongful opportunity had been given. The present mayor of Tamworth and his friends may have all the admirable sanitary intentions with which Mr. Allkins credits them (presumably Mr. Allkins is one of the friends), but this will not alter the fact that the public health of this country has to be carried out by the people appointed under the Acts of Parliament and in accordance with those Acts. A well-intentioned mayor is not necessarily an expert sanitarian and to be the friend of a mayor is not to be in possession of a diploma in public health. We could not have desired a fuller confirmation of the correctness and accuracy of our views, when dealing with the situation at Tamworth, than Mr. Allkins supplies.—ED. L.

THE SILICO-FLUORIDES IN OTORRHŒA.

To the Editors of THE LANCET.

SIRS,—A few weeks ago you kindly published a letter in which I brought forward the value of otectomy and the silico-fluorides in the treatment of otorrhœa. In the interests of my crusade against the lamentable ignorance so often exhibited in regard to this disease I may perhaps be allowed to allude to three cases that illustrate the dangers that threaten the unchecked course of suppurative otitis. They were admitted to the Coventry Hospital at the beginning of last week. Case 1, aged four years, who had been under occasional medical treatment for otorrhœa, was sent in for meningitis. The child was in a semi-comatose condition with a high temperature. A slight discharge came from the right ear and from a sinus behind the ear. The temporo-sphenoidal lobe was searched without much result. The bone exposed was greenish in hue. The child died on the third day. Case 2, aged 12 years, had been under medical care for three years for a "running ear." There had been intense pain, but the case was not sent [illegible] there were rather alarming symptoms. The [illegible] was about 103° F. and the child looked very [illegible] There was a sinus behind the ear. Otectomy was performed and the antrum was opened, diseased bone being removed. The case is now doing well. Case 3, aged seven years, was sent in for otorrhœa. This middle ear was full of growths, the discharge being foul—a dangerous condition from which the patient was relieved by otectomy and is doing well.

I ask, Sirs, if the above cases admitted at a small hospital within a few hours of each other do not justify a protest against the prevailing indifference with regard to "running ears." Almost every week I see cases that bear witness to neglect or inefficient treatment. Yet it is certain that such cases can almost always be cured by proper treatment.

I am, Sirs, yours faithfully,

F. FAULDER WHITE.

Coventry, July 1st, 1904.

THE AGGLUTINATION REACTION IN TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if any of your readers [illegible] e whether they have ever observed such a [illegible] of the [illegible] describe. [illegible] two [illegible] disease, which clinically resem[illegible] a most remarkable effect on an emulsion of active typhoid bacilli. When the serum was added to the bacilli in the proportion of 1–20 they were found to become much more actively motile. In fact, I have never seen such an extreme degree of motility a

occurred in these reactions. I have employed the agglutination reaction with various micro-[illegible]
cases both in man and animals
such a condition in the cases a
not seen it recorded i[illegible]

I am,

July 6th, 1904.

PROPOSED TESTIMONIAL TO DR. EYRE.

To the Editors of THE LANCET.

SIRS,—In August, 1903, Dr J. Eyre was investigating some points in the biology of the micro-organism of Malta fever in the bacteriological laboratory at Guy's Hospital when he accidentally inoculated himself with this micro-organism. A few days afterwards he developed an attack of Malta fever, causing incapacity for work for six weeks. As he was insured in a company against accidents and several diseases, including septicæmia, he made a claim under his policy. As he had been given to understand by the agent who induced him to take out the policy that it included accidental bacterial infections, contracted in his laboratory, he was astonished to find his claim repudiated. Acting on the advice of counsel Dr. Eyre insisted on his claim, and the dispute, owing to a clause of the policy, had to be decided, not publicly in court but by private arbitration. The decision of the arbitrator was in favour of the company. This decision is, I think, one of great importance to members of the medical profession who hold accident policies. Dr. Eyre's costs for the arbitration amount to some £140 and it is thought by many of his friends, amongst whom I count myself, to be a fitting opportunity to present him with a testimonial in order to assist him in meeting these costs. Cheques may be sent addressed to me at Guy's Hospital.

I am, Sirs, yours faithfully,
J. H. BRYANT.

Mansfield street, Portland-place, W., July 7th, 1904.

*** Dr. Bryant incloses a list of subscribers of sums varying between £3 3*s.* and 10*s.* 6*d.*, showing that the medical profession are recognising the hardship which Dr. Eyre has undergone. The circumstances will be found in detail in THE LANCET of June 25th, p. 1811. We shall publish the list of subscribers next week —ED. L.

ACCIDENTAL VACCINIA OF THE NASAL CAVITY.

To the Editors of THE LANCET.

SIRS,—Mr. W. H. Bowen's account of a case of the above in THE LANCET of July 2nd, p. 20, exactly describes a case I had some years ago, except that in my case I found a well-marked vesicle inside the ala nasi. Shortly afterwards I had a similar case in which the vesicle appeared on the lower lip. Both were women and no trouble ensued.

I am, Sirs, yours faithfully,
Stonebroom, Alfreton, July 5th, 1904. R. M. H. WALFORD.

IN THE MATTER OF PATENT MEDICINES.

To the Editors of THE LANCET.

SIRS,—I should be greatly obliged if you could give an authoritative answer to the following questions. May a medical man if he knows the composition of any *patented* proprietary article prescribe its exact formula so as to have it made up as an ordinary prescription or is a hospital dispenser legally entitled to make up any proprietary article of which he can discover the formula or composition? If the general answer to these two is in the affirmative would the answer also be in the affirmative if the article in question could only be made by special patented *process?*

I am, Sirs, yours faithfully,
July 4th, 1904. INQUIRER.

VACCINATION GRANTS.—Mr. J. D. Staple, public vaccinator of the Ashley district of the Bristol union, has been awarded the Local Government Board grant for successful vaccination for the fourth consecutive year.—Dr. A. W. Woodman Dowding has obtained the grant for successful vaccinations in the St. Newlyn East district of Cornwall.

THE INTERNATIONAL HEALTH OFFICE.

PROGRESS AND MODIFICATION OF THE PROJECT.

(BY OUR SPECIAL SANITARY COMMISSIONER.)

Paris, July 4th.

AT the last official International Sanitary Conference which met off and on in Paris from Oct. 10th to Dec. 3rd, 1903, a resolution was adopted in favour of constituting a permanent International Sanitary Office. This proposal, as related at the time, was not unanimously approved and the representatives of the British Government notably made some reservations. Since then there has been time for reflection, for a further exchange of views, and for a better understanding of the project. The idea has been ripening and within the last few days a distinct step forward has been taken. On the other hand, there has been no undue haste. For more than half a century various governments of Europe have held international conferences on sanitary matters. There have been in all 11 such official gatherings and it cannot be said that they have overburdened the world with proposals, schemes, and projects of legislation. The first conference met at Paris in 1851 and 12 nations were represented, the last conference met in 1903, also at Paris, but there were no less than 24 nations and governments represented The earlier conferences were more like scientific gatherings. The governments were represented by diplomatists who held a sort of watching brief while men of science discussed. Motions were carried and pious wishes were expressed. This sort of platonic procedure prevailed at the conferences held in 1851 at Paris, in 1859 at Paris, in 1866 at Constantinople, in 1874 at Vienna, in 1881 at Washington, and in 1885 at Rome. At Vienna in 1892 a considerable change took place. Europe was then menaced with the cholera and now the representations of the various governments began to take action. Conventions were signed and the conference met again the next year at Dresden and again, the year following (1894) at Paris. Later, in 1897, the tenth International Official Conference was held at Venice and this time for the purpose of drawing up an international convention in regard to the precautions which were to be taken to prevent the spread of plague. Thus out of 11 conferences only the last five have resulted in the signing of international treaties and agreements. It may be said that, while the first conferences met to discuss theories and to study sanitary problems this task has of late years been relegated entirely to the international medical and sanitary congresses. The official conferences, therefore, now meet, not to discuss theories, but to legislate; the debates relate to the regulations that it may be thought wise and possible to impose and to the international conventions that are necessary for such purpose So far the object of such understanding was to prevent the spread of disease from one nation to another while at the same time striving to reduce the inconvenience of such precautions, notably of quarantines, to the lowest possible degree.

These various agreements were grouped together and codified at the conference held in Paris last year. The new convention thus drawn up, which codifies and ratifies all the prev[illegible] 3rd, 1903, and is divi[illegible] or articles. But this [illegible]ly codifies, it also modifies the measures to be taken so as to bring them in harmony with the more recent discoveries of science. For instance, it is now believed that the period of incubation for plague is only five days, so that the period of observation of the passengers coming from a ship where there has been cases of plague on board has been reduced from ten to five days. Also it is now no longer necessary in such a case to retain the passengers in quarantine for these five days: they can be allowed to proceed if they are going to a place where there is a competent sanitary administration which can keep them under efficient observation. Then, again, according to the Venice Convention, every government had to notify to all the governments which had signed the convention whenever a case of plague occurred. *But if this case came from abroad and the disease did not spread to inhabitants of the country then it was not necessary to take any measures against the district in question.* In practice many authorities failed to notify the first case and only all that has been said concerni [illegible] perties of the blood has been [illegible] notion. Either of these attempted [illegible] over, be equally at variance with [illegible] the beneficent practice which he initiated. Such suppositions are, in fact, condemned by the life-saving results of his practice. Had either of the above attempted explanations of the fact that bacteria can be made to appear at will within the tissue elements of previously healthy organs been true—explanations, that is, which suppose that such organisms or their germs exist as such during life in the organs of healthy animals—then, as I have already indicated, the efforts to procure asepsis, as now practised by surgeons all over the civilised world, would be solemn but unreasoning mockeries and nothing else.—I am, Sirs, yours faithfully,

H. CHARLTON BASTIAN.

Manchester square, W., July 4th, 1904.

IN THE MATTER OF THE TAMWORTH TOWN COUNCIL.

To the Editors of THE LANCET.

SIRS,—My attention has just been drawn to some remarks you make in your issue of June 18th relative to the Tamworth town council and its medical officer's report. Perhaps you will permit me to say that your remarks show that the information you have received, and upon which you have based your remarks, is *absolutely incorrect* and *misleading*, and has no doubt been supplied to you from some "official" source with the view of using *your* weighty *opinion* to bolster up the official's cause. At the time I moved the resolution in the council—"That the medical officer's report be submitted to the chairman of the sanitary committee before being printed"—I had no wish, as I explained to the council at the time, to in any way *revise* or *alter* the report *and the medical officer has never been asked by the council or the mayor* to *omit* anything from his report. The chairman of the sanitary committee, I believe, did suggest some alteration in the manner or the language in which the doctor had expressed his views on some very minor matter but no attempt whatever was made, as you suggest, to get the doctor to alter or omit anything from his report that would in any way conceal anything from the Local Government Board or county council; in fact, the present Mayor of Tamworth and his friends on the council will be very glad if the medical officer of health will wake up a bit and send in his reports at the proper time and not three or four months after date and after repeated requests for the same from the authorities you quote; also they will be grateful to him if he will show up all the weak spots in the *sanitary state* of the town and not devote so much space in his reports to ornithological essays, &c. The present Mayor of Tamworth and his friends are doing, and intend to do, all in their power to push on with a thorough policy of sanitary reform including an up-to-date system of sewerage and sewage disposal. Perhaps you will also permit me, too, to suggest to you the advisability of ascertaining that any information sent to you from Tamworth is correct before you proceed to criticise adversely the doings of the Tamworth town council or its mayor. The Tamworth people know more about Tamworth's requirements than does the Editor of THE LANCET and also they know who are the most likely men to study their interests. They also know that if any apology is due to anyone it is due from the doctor to the sanitary committee for the wanton and unnecessary manner in which he insulted it. Finally, I would like just to say that the mayor of Tamworth has the support of the majority of the ratepayers of the borough in his praiseworthy efforts to re [illegible] the hands of the "officials" who f [illegible] exercised their ingenuity in looking after number one with the most baneful effect on the public spirit of the town. The present mayor, by his great administrative ability and strict economy, has been able to reduce the rates of the borough in three years from 8*s*. 1*d*. in the pound to about 6*s*. 5*d*. without sacrificing efficie [illegible] thus making it possible to carry [illegible] sposal and many other greatly-needed measures of reform.

I am, Sirs, yours faithfully,

Hill Crest, Tamworth. T. B. [illegible]

*** We received th [illegible] We publish it in spit [illegible] Mr. Allkins with genial observance of the ordinary courtesies of life to be "absolutely incorrect and misleading," pointed out that it was well that the medical officer of health of Tamworth had obeyed the law and submitted his report to the Local Government Board instead of allowing it to be supervised by the Tamworth town council. In consecutive sentences Mr. Allkins says (1) that he moved for the medical officer's report to be submitted to the chairman of the sanitary committee before being printed, having no wish that the report should be revised and altered; and (2) that the chairman of the sanitary committee suggested alterations. It seems to us that those alterations would probably have been made if the wrongful opportunity had been given. The present mayor of Tamworth and his friends may have all the admirable sanitary intentions with which Mr. Allkins credits them (presumably Mr. Allkins is one of the friends), but this will not alter the fact that the public health of this country has to be carried out by the people appointed under the Acts of Parliament and in accordance with those Acts. A well-intentioned mayor is not necessarily an expert sanitarian and to be the friend of a mayor is not to be in possession of a diploma in public health. We could not have desired a fuller confirmation of the correctness and accuracy of our views, when dealing with the situation at Tamworth, than Mr. Allkins supplies.—ED. L.

THE SILICO-FLUORIDES IN OTORRHŒA.

To the Editors of THE LANCET.

SIRS,—A few weeks ago you kindly published a letter in which I brought forward the value of otectomy and the silico-fluorides in the treatment of otorrhœa. In the interests of my crusade against the lamentable ignorance so often exhibited in regard to this disease I may perhaps be allowed to allude to three cases that illustrate the dangers that threaten the unchecked course of suppurative otitis. They were admitted to the Coventry Hospital at the beginning of last week. Case 1, aged four years, who had been under occasional medical treatment for otorrhœa, was sent in for meningitis. The child was in a semi-comatose condition with a high temperature. A slight discharge came from the right ear and from a sinus behind the ear. The temporo-sphenoidal lobe was searched without much result. The bone exposed was greenish in hue. The child died on the third day. Case 2, aged 12 years, had been under medical care for three years for a "running ear." There had been intense pain, but the case was not sent to us until there were rather alarming symptoms. The temperature was about 103° F. and the child looked very ill indeed. There was a sinus behind the ear. Otectomy was performed and the antrum was opened, diseased bone being removed. The case is now doing well. Case 3, aged seven years, was sent in for otorrhœa. This middle ear was full of growths, the discharge being foul— [illegible] from which the patient was relieved by [illegible] well.

I ask, Sirs, if the above cases admitted at a small hospital within a few hours of each other do not justify a protest against the prevailing indifference with regard to "running ears." Almost every week I see cases that bear witness to neglect or inefficient treatment. Yet it is certain that such cases can almost always be cured by proper treatment.

I am, Sirs, yours faithfully,

Coventry, July 1st, 1904. F. FAULDER WHITE.

THE AGGLUTINATION REACTION IN TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if any of your readers could inform me whether they have ever observed such a peculiar feature of the reaction as I am about to describe. The serum from two [illegible] from some disease, which clinically resem [illegible] produced a most [illegible] effect on an emulsion of active typhoid bacilli. [illegible] erum was ac [illegible] ey were found t [illegible] I have never seen such an extreme degree [illegible] necessary promptitude even were it desirable that it should take such a service in hand The consuls will continue to inform their respective countries when anything which they consider to be dangerous occurs in the towns where they are stationed But the International Health Office will collect such information as will enable the governments to know better how to act when they receive warnings from their consuls As it is the rules laid down in the conventions are the same for all countries and this greatly to the disadvantage of Great Britain For instance if a ship arrives from Glasgow, London or Liverpool and there have been one or two cases of plague in these ports the same precautions can be enforced against such a ship as if it were a Turkish vessel coming from a port in the Levant where there is no sanitation whatsoever and where a violent epidemic of plague prevails

The object of the International Health Office is not merely to collect statistics It will seek to gather information in regard to all sanitary legislation and measures Thus the difference between London Liverpool and Levantine ports will be rendered evident to all whose business it is to study such matters and consequently it will be possible to differentiate in the treatment of vessels according to whether they come from countries where there is good or bad sanitation In such comparisons the advantage will be altogether on the side of Great Britain The same may be said in regard to such sanitary legislation as the Factory Acts the Ten Hours Bill and so on The object is to prevent the hindrance of sanitary legislation by the fear of foreign trade competition

All these matters having now been gone over thoroughly and all groundless fears it is hoped finally removed a new text for the project has been drawn up This is so worded as to prevent the possibility of the exchange of pin pricks between the nations concerned The modifications in the text have been introduced so as to remove all opportunity of unfair advantage being taken in regard to notifications of disease Therefore clean countries with adequate statistics will run no risk of being punished because they have instituted the compulsory notification of disease There is besides *no compulsion about the scheme The governments* will only supply what information they deem it advisable to supply Nevertheless it is anticipated that there will be enough information forthcoming to constitute a powerful stimulus to backward countries and to help to bring them into line

At all events the project is now ripening The decision of the conference of 1903 was that the French Government should forward propositions through diplomatic channels to the different States These proposals had however to be supplied by its own technical department This I have good reason to believe has been done within the last few days and the French Minister of Foreign Affairs (M Delcassé) is now in a position to supply the foreign governments with the text of the proposals as modified so as to prevent misunderstanding together with other indispensable details

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

The Animal Scavengers of Indian Cities —The Health of Bengal in 1903 —The Plague Epidemic

IT has generally been held that crows kites vultures jackals and pariah dogs are all very useful animals in an Indian town by feeding on the refuse and thus diminishing the amount which would decompose and have to be carted away An opinion has been growing up of late however that in cities they are not only a nuisance but may do more harm than good In a village refuse is deposited and left to every natural agency for its disposal In the small towns also there is hardly any attempt at conservancy Even in the large towns it is very indifferently carried out and it is only in the cities that any properly organised removal of rubbish and cleansing of the streets are in force In a large city animal scavengers cannot be calculated upon and it is found that they scatter rubbish about and distribute it in undesirable places In Calcutta an order has gone forth to destroy crows eggs and the question has also come before the Rangoon municipality The crows and kites are certainly the worst offenders but in some towns vultures also scatter as well as consume In addition the crows are by their noise and thieving capacities a public nuisance The danger of these birds lies in their habits of disseminating putrid filth and many a store of drinking water is poisoned by bits of refuse dropped from beak or claws while on the wing It may be said that where there is deposited refuse there the scavengers will be numerous and it speaks ill therefore for a city which is infested with crows They are not substitutes even for defective conservancy they are not necessary and as many eastern towns prove they can be done without

The report of the Sanitary Commissioner of Bengal for 1903 has just been issued It shows that the birth rate of this large and populous province is nearly 40 per 1000 and that the death rate is about 33 3 per 1000 More accurate returns and the comparative figures for the jails show that tuberculosis is much more common among the natives than was formerly supposed Infantile mortality is very high and a partial inquiry into some 2000 cases indicated that nearly 40 per cent of the deaths were due to malpraxis about the same percentage to malnutrition and nearly 20 per cent to mismanagement of labour and diseased parentage There was a great and widespread increase of small pox but the *vaccination department* can hardly be considered satisfactory and is to be reformed Little or nothing has been done in the direction of the destruction of mosquitoes but the jail superintendents are to take up this matter as an object lesson for the province It is recorded that 65 680 deaths occurred from plague in *Bengal* in 1903 and it is questioned whether more medical relief could not be furnished especially in the infected towns

The India is rapidly subsiding For th ere were 13 770 deaths as compa evious seven days The provincial figures are Punjab 12 269 deaths as against 18 086, United Provinces 420 as against 653 Bombay districts 547 as against 768 Bengal 129 as against 200 and Kashmir 81 as against 74 The last returns from Bombay city and from Calcutta are also much more favourable Instances of the irregularity of outbreaks and recurrences are shown by Benares which in the past cold weather has been practically free and by Mirzapur which was also badly infected in 1902 escaping almost entirely last year Now that the annual recrudescence is subsiding it is suggested by one of the leading European papers that the Government should institute an exhaustive scientific inquiry into the cause of plague and the life of the bacillus outside the human body At present the sanitarian is practically helpless and he will continue to be so until we learn more about the disease

June 17th

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Health of Liverpool in 1903 Annual Report of the Medical Officer of Health

THE report of Dr F W Hope the medical officer of health on the health of Liverpool during 1903 has just been issued It is comprised in a volume of 238 pages illustrated by many maps and diagrams and contains a mass of vital statistics The city covers an area of over 23 square miles and has a population of 716 810 During 1903 the death rate 19 8 per 1000 of the inhabitants per annum was the lowest yet recorded There were 1090 fewer deaths than in 1902 The rate varied greatly in different districts In Sefton Park it was only *9 per 1000* whilst *in the Exchange* division it was 30 per 1000 The birth rate 33 3 per 1000 showed equal diversity It was 42 9 per 1000 in the Scotland division and in the Sefton Park district it was only 19 3 per 1000 On the other hand the infant death rate in the Scotland division was 215 per 1000 and in Sefton Park 88 per 1000 The greater part of the infant death rate was preventable Of 3815 deaths of infants under one year of age 627 died from atrophy and 763 from zymotic diseases Ever since 1873 there has been a steady increase in the mortality due to premature birth *92 infants were overlain* by their mothers During 1903 there was a serious outbreak of small pox The cases numbered 2032 141 being fatal The compulsory notification of chicken pox resulted in the discovery of 54 cases of small pox being mistaken for the former disease Typhus fever spread from an insanitary area since dealt with occasioned 272 fatal. There were 4053 cases of scarlet fever and 201 deaths; 27,289 cases of measles and 132 deaths; and whooping-cough caused 318 deaths (but this figure is by no means a complete representation of the mischief caused by it). Zymotic diarrhœa caused the deaths of 657 persons (almost all in the poorer and crowded districts), 461 being infants. Phthisis also carried off 1258 persons; 2067 cases were reported during the year. 170 persons died from alcoholism. Dr. Hope advocates hospital treatment for whooping-cough and an amendment of the Vaccination Acts in the direction of stringency. The deaths from small-pox in England are, he stated, nearly 20 times as many as in Germany where vaccination is strictly enforced. Part of the policy of the health committee is the abolition of ash-bins. Owing to demolitions 1123 insanitary courts have disappeared during the last 13 years. The city contains 558 registered lodging-houses, accommodating 14,091 lodgers; these are under close sanitary supervision. 21,719 houses are registered as sublet. During the year the health committee has had new duties thrown upon it, including the registration and supervision of midwives, the inspection of bakehouses, and the enforcement of the Employment of Children Act, which prohibits the employment of any child under 14 years of age. Great attention has been paid to the supply of milk; the daily consumption is 30,000 gallons. Inspection both of city shippons and farms supplying milk has been systematic. The lower death-rate of the city is due almost wholly to the saving of the lives of children owing to measures taken for the prevention as far as possible of infantile disease. The death-rate of infants during 1903 was 159 per 1000; during the three years preceding the average per 1000 was 178. At the same time the death-rate above one year of age has fallen from 16·7 per 1000 to 15 per 1000. 6295 infants have been fed on the milk supplied from the sterilised milk depôts and with the most satisfactory results, for although these children were to begin with below the average in health the death-rate among them was only 78 per 1000. The city hospitals for infectious diseases accommodated 925 patients. They were usually full; indeed, if it had not been for the incessant activity of the medical officer's staff, together with stringent scavenging, the population would be decimated by disease. In combating the outbreak of small-pox the department showed the greatest vigilance. At the meeting of the health committee held on June 30th the chairman remarked upon the declining death-rate, stating that the mortality during the present year (1904) was, so far, still more favourable.

University of Liverpool: First Public Conferring of Degrees.

The ceremony of conferring degrees on new graduates of the University of Liverpool took place at St. George's Hall on July 1st. This being the first public function of the kind which has taken place in the city it was decided to invest it with due impressiveness and in that respect the proceedings did not fall below anticipation. Both the body and the galleries of the hall were crowded with a representative assemblage of between 3000 and 4000 people. While the public were arriving the graduates and others, in academical costume, were marshalled in the west corridor, according to the faculties to which they belonged, Dr. Peace (the city organist) at the great organ playing selections during the interval. At noon the procession entered the hall, headed by the registrar, and proceeded to the allotted seats. It comprised graduates of the faculties of engineering, laws, science, and arts, including both new graduates and graduates of the Victoria University, who, under the provisions of the charter, had accepted an equivalent or taken a higher distinction in the University of Liverpool. Of the latter there were about 300. All wore costumes of the new University, a hood lined throughout with coloured silk, edged, in the case of bachelors, with white fur. The distinctive feature of the costume is that the robe is edged with silk of the same colour as the hood. There is, of course, a different colour for each faculty. Following the first section of the procession, the members of which were accommodated with seats in the body of the hall, there came a second, preceded by ushers and formed of graduates in medicine, Victoria graduates in laws, masters of engineering, masters of arts, and doctors of science. For these places were provided on the platform. They in turn preceded the members of the court [illegible] of the teaching body, and the council [illegible] Lord Mayor, the treasurer of the University, the pro-Chancellors, the Vice-Chancellor, and finally the Chancellor (the Earl of Derby). The Chancellor wore the costume of a doctor of laws. The first proceeding was the presentation of the Earl of Derby for the degree of doctor of laws. His lordship was presented to the Vice-Chancellor by Professor MacCunn who eulogised the many high qualities of the noble earl. The Chancellor in his reply said that they were in a position at last of being able to have a general admission of degrees—the first in the annals of the University. They had amongst them many who would receive honorary degrees and degrees of that University who had acquired their qualifications in University College and obtained their degrees in the University of which Liverpool was then only a part. Many graduates of Victoria University would be presented that day. Referring to the munificence of donors his lordship remarked that the Treasury had made their University a grant of £2000 a year, promising to increase that amount to £3000 at some future time. The Liverpool City Council showed its appreciation of the benefits that would accrue from the foundation of the University by granting £10,000 a year, £1000 of which are reserved for scholarships. The borough of Bootle had granted them £500 a year, half of which was to be expended in scholarships. They had during the last week been promised £10,000 by a friend who wished to remain unknown for the purpose of [illegible] English language. The family of the late [illegible] had given £1000 to found an entrance scholarship in arts, whilst Mr. W. Thelwall Thomas and Dr. G. Stopford Taylor had established fellowships for a term of years in medical subjects. He believed the University had before it a lengthy and brilliant career in training those who wished to make their own path in life as well as in advancing science, art, and all that tended to the higher life of man. He concluded by assuring his hearers that in his new capacity as Chancellor of the University he would do all in his power to advance the honour a[illegible] University. Lord Derby then formally [illegible] who were introduced by the deans of the respective faculties. The ceremony was incorrectly described in the local papers as the first function of the kind held in the city, as on March 25th (as described in THE LANCET of April 2nd, p. 960) four students were presented to the Vice-Chancellor (in the absence of the Chancellor) in the Tate Library of the University by the dean of the medical faculty and admitted to the degrees of bachelor of medicine and bachelor of surgery.

Liverpool University Association: Banquet to Dr. Londini.

Dr. Londini, who has recently resigned the office of registrar of the University of Liverpool to take up that of bursar, was entertained to dinner by the University Association at the Adelphi Hotel on June 30th, this being the second dinner of the association. Vice-Chancellor Dale presided. The chairman presented Dr. Londini on behalf of the association with a purse of gold and an address couched in poetic and jocose language. Dr. Londini suitably acknowledged the gift.

(FROM OUR OWN CORRESPONDENT.)

Edinburgh Company, Royal Army Medical Corps Volunteers: Presentation to Surgeon-Major D. Hepburn, 3rd Welsh Volunteer Battalion.

THE eighteenth annual dinner of this Company was held on June 29th in the Carlton Hotel, Edinburgh, when a presentation, subscribed for by past and present members, was made to Surgeon-Major Hepburn, the former commanding officer of the company. Between 70 and 80 members and guests were present, and among the latter were Colonel G. A. Hughes, D.S.O., R.A.M.C., principal medical officer of the Scottish district, Major J. Scott, R.A.M.C., Major Hope, Q.R.V.B., Surgeon-Captain C. B. Ker, Q.R.V.B., Mr. Cathcart, and other officers and friends. The chair was taken by Lieu[illegible] Waterston, the commanding officer, who made the [illegible] and in doing so [illegible] entertained towar[illegible] present mem[illegible]ld-wide, inclu[illegible] Australia, Canada, [illegible] the presentation, which took the form of a gold watch, Surgeon-Major Hepburn expressed the sincere regret which he had felt in severing his connexion with a company with which he had so long and pleasant a connexion. A very enjoyable evening was spent. The other speakers included Colonel Hughes and Mr. Cathcart, who was the first commanding officer of the company.

July 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Ulster Medical Society.

THE annual meeting of this society was held on June 30th in the Belfast Medical Institute. The reports of the secretary, the treasurer, and the librarian were presented and passed. There are now 150 Fellows and 36 members, making with the honorary and life members a total membership of 197. Nine meetings were held during the session with an average attendance of 43. There is a balance of £52 14*s*. 3*d*. and £50 have been invested in the Transvaal Loan. The following office-bearers were elected for next session: President, Professor J. Lorrain Smith; vice-presidents, Dr. J. B. Moore and Dr. W. E. Hadden (Portadown); secretary, Dr. T. Houston; treasurer, Dr. W. B. McQuitty; librarian, Dr. R. R. L. Leatham; members of council in addition to the seven permanent trustees, Dr. J. S. Morrow, Mr. R. Hall, Dr. D. J. McKinney, Dr. D P Gaussen, Dr. J. R. Davison, and Dr. W. L. Storey. Sir William Whitla presented to the Medical Institute, on behalf of Mrs. Gordon Stallard, a portrait of her father, the late Professor Gordon, which was unveiled by Mrs. John Campbell, wife of the President of the Ulster Medical Society, and accepted by the President. A vote of thanks to the donor was passed on the motion of Professor T. Sinclair, seconded by Dr. J. Nelson.

The Health of Belfast.

At a meeting of the city council of Belfast held on July 1st an important discussion took place following the report of the public health committee. It appears, in reference to the small-pox epidemic, that 94 cases had been admitted into the Purdysburn small-pox hospital, three had died, and 36 were still remaining on July 1st. Ample accommodation has been made for more and a resident physician has been appointed. The people had been urged to have themselves revaccinated. In the discussion one of the councillors (a medical man) spoke of the epidemic as "only of a trifling nature" but was corrected by the
chairman of th
man) who said
It is said that
rashes, that thr
man has taken
hospital. The
forward by one
tained that "defective foundations of houses, insufficient supply of pure water, and bad ventilation" were the causes of small-pox. It is gratifying to know that the public are responding largely to those who urge revaccination as the proper thing to be done, and it is hoped that the epidemic will soon be stamped out. As an evidence of the efficacy of revaccination it was pointed out that 39 out of 40 "contact" cases were revaccinated. These 39 escaped the small-pox while the one not revaccinated contracted the disease. Of the whole staff of the public health department only one contracted small-pox and that

The Mater Infirmorum Hospital, Belfast.

The collection on behalf of this hospital on Saturday, June 25th, amounted to more than £800.

Sanatorium for Consumptives.

At a joint meeting of the Belfast public health committee and representatives of the board of guardians held on July 4th it was agreed that the corporation should be recommended to take immediate steps to provide for the erection of a sanatorium to accommodate cases of pulmonary tuberculosis which there may be reasonable expectation of curing, while the guardians on their part undertake to proceed with the provision of an auxiliary workhouse building for the care of the destitute poor who may suffer from the disease, it being understood that so far as possible the corporation will take over from them as paying patients cases which come under the category of "primary" or "hopeful" cases of the disease.

Sanitary Condition of Portadown.

Dr. C. J. Clibborn (Local Government Board inspector) reports on the defective sewerage of the district, on the need of a suitable ambulance for the conveyance to hospital of patients suffering from infectious disease, and on the desirability of providing a properly equipped disinfecting apparatus for the use of the locality. He also says that the water-supply is bad and inefficient and recommends the adoption of the Infectious Diseases (Prevention) Act, 1890. The report was considered at a meeting of the Portadown town council on July 4th.

July 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis among School Children.

AT the meeting of the Academy of Medicine held on June 21st Professor Grancher discussed this subject in an address which has produced a sensation and will mark an epoch in the history of tuberculosis. Assisted by some of his pupils he examined all the children in two of the schools of the city of Paris, the result being that in 14 per cent. of the boys and 17 per cent. of the girls he found positive signs of tuberculosis of the glands either of the neck or of the trachea and bronchi; half these children, already showing slight bacillary infection, were the offspring of tuberculous parents. All taken together, out of 896 children 141 were

symptoms of tuberculosis sooner or later. Professor Grancher made trial of dietetic treatment with some success. A small sum provided by the city enabled him to have a daily supply of meat powder and cod-liver oil issued to the affected children in the two schools which he had examined, and he

the patients suffering from pronounced tuberculosis and the results would be no more than moderately successful.

Reduction of Congenital Dislocation of the Hip-joint by the Paci-Lorenz Method.

At a meeting of the Société de l'Internat des Hôpitaux de Paris held on June 23rd, M. Monnier, after remarking that not many years ago congenital dislocation of the hip-joint was regarded as incurable, said that the case was quite different now provided that the children were not more than eight years of age or ten at the outside, and provided that, as

—namely (1) firm pressure from above
thigh being strongly flexed on

months. Under chloroform the limb was then set at an angle of 45° and fixed in that position by a plaster splint for three months more, after radiography had shown the permanence of the reduction. In the sixth month another plaster splint (the third) was applied, the legs being now almost parallel. In the eighth or ninth month, up to which time the child had remained constantly in bed, the splints were removed, massage was used, and walking exercise was taken. In support of what he had said M. Monnier referred to the cases of two little girls who had recovered perfectly under this treatment. One of them, who suffered from dislocation of both hips, had double reduction performed at one operation when she was three years of age; the heads of the femora as seen in a radiograph were dislocated to the extent of 18 or 20 millimetres. The second patient who came under treatment at the age of four years had a dislocation on the left side with a shortening of 25 millimetres. It was, however, necessary to classify these cases, for with a boy of six years, the heads of whose femora as seen in a radiograph were of great size and considerably raised, efforts at reduction were continued for 45 minutes without success. The Paci-Lorenz method would only give good results when the cases were selected.

Therapeutic Action of Sugar.

At a recent meeting of the Therapeutical Society M. Toulouse gave an account of his investigations on the dietetic value of sugar in the various morbid conditions in which emaciation required to be treated. For this purpose he gave large quantities of sugar in addition to the food which might consist of either ordinary diet or milk diet. The sugar varied in amount from 50 grammes to 300 grammes (from one and three-quarters to ten ounces) a day, representing in the case of emaciated women as much as eight grammes of sugar per kilogramme of body weight. From the commencement of the treatment the patients gained in weight on an average 100 grammes a day; with some of them the gain was sometimes 500 grammes, being therefore greater than the weight of the sugar that had been taken. Some patients in a few months increased from 35 to 48 kilogrammes. Whilst the sugar was being given examination of the urine generally showed a diminution in the amount of the nitrogenous constituents without their relative proportions being sensibly altered. The action of the sugar was at its maximum when the patient was on milk diet and taking three litres of milk per day. On theoretical grounds gastric fermentation and disorders of digestion might have been expected from the use of so much sugar but no unpleasant effects of that kind were observed. The sugar did not pass into the urine in healthy individuals. These experiments showed that sugar was a therapeutic agent of great activity in all conditions of marked emaciation and that it did not disagree even with patients whose assimilation was imperfect in consequence of disorders of digestion.

Hypochloridation and Hyperchloridation without Bromide in Epilepsy.

At a meeting of the Société Médicale des Hôpitaux held on June 17th M. Toulouse said that since he had shown, in conjunction with M. C. Richet, the influence of chloride of sodium on the action of bromide in the treatment of epilepsy a great number of investigators guided by various considerations had demonstrated the importance of chloride of sodium in connexion with osmotic equilibrium and therefore as a factor in the general nutrition of the organism. In these circumstances it might become a question whether the hypothesis advanced by M. Toulouse and M. Richet in explanation of the new fact which they had brought to light was really the most probable explanation. These two observers supposed that when the tissues were no longer supplied with chloride their affinity for this salt and (in its absence) for allied substances would render them more susceptible to bromide. There might, however, be another explanation. The salt might perhaps in these experiments act by itself apart from the bromide and, for example, by producing alterations in the osmotic tension might affect the vitality of the tissues, especially the nerve tissue, and bring about conditions more favourable to epilepsy. M. Toulouse resolved to take up this question and to inquire whether the giving of salt in excess or the limitation of it appeared to have an effect on the progress of the disease in epileptics, some on milk diet and some on ordinary diet, but not treated with bromide. He now informed the society that he had found that daily quantities of chloride of sodium, varying from two to 25 grammes and given alternately to the same patients at periods when all the other conditions remained constant, had no effect on the frequency of the epileptic attacks. These negative results were important, for they narrowed the available explanations of this new fact so interesting in general pathology.

Monuments to Men of Science.

M. Charles Girault has handed over the Pasteur monument to the managing committee of the Pasteur Institute and it has been decided that the inauguration ceremony shall take place on July 16th. The President of the Republic has been invited by Dr. Roux, director of the Pasteur Institute, and has promised to be present. All the great officers of State will therefore attend and an invitation has been sent to the Institut de France.—On June 26th a memorial to Professor Panas was unveiled with much less ceremonial display at the Hôtel-Dieu. M. Panas was the first professor of ophthalmology in this hospital. The memorial is by the sculptor André Boucher and represents the late professor seated in the consultation room and having at his side a blind child, towards whom he is reaching out his hand preparatory to examining it. A commemorative medal has also been struck, showing on one side the features of M. Panas and on the other side the figure of Science raising a bandage from the eyes with the inscription—

> Arte et studio e tenebris in lucem revocat.

Several addresses were delivered, including one by the Dean of the Faculty of Medicine and the proceedings terminated with a speech by M. Chaumié, Minister of Public Instruction.

July 5th.

NEW YORK.

(FROM OUR OWN CORRESPONDENTS.)

The American Medical Association.

THE fifty-fifth annual meeting of the American Medical Association opened in Atlantic City on June 6th. The place of meeting was peculiarly well adapted for the purpose both by situation and by its facilities for accommodating and entertaining a large number of people. The House of Delegates held a session on June 6th, when the retiring president, Dr. Frank Billings of Chicago, occupied the chair.—Dr. George H. Simons of Chicago, the secretary, reported that the membership of the association in June, 1903, was 13,545, that 2413 new members had been added during the past year, and that 919 had been dropped on account of death, non-payment of dues, and other causes. The membership on May 1st, 1904, was 15,039.—Dr. Arthur D. Bevan of Chicago, speaking on the report of the committee on medical education, said that owing to the nature of the United States Government no help could be expected from that source in raising the standard of medical education but they must depend entirely on the efforts of a well-organised association.—Dr. C. A. L. Reed of Cincinnati, Ohio, speaking on medical legislation, said that they had arranged to have a correspondent in every county in the United States. They had succeeded in getting 1940 such correspondents and had issued commissions to each, urging them to use all means in their power, both political and personal, to secure such legislation as the association should desire. They had made an effort to secure the appointment of a physician on the Panama Canal Commission. They had secured the passage of the Bill giving the marine and navy hospitals nurses and dentists. Their request that a representative of the medical corps should be detailed to serve on the general staff of the army had been granted. The entire profession was urged to make an effort to have physicians nominated and elected to Congress, as the lack of such representation was the most serious obstacle encountered in their efforts on behalf of the public welfare and of the profession itself.—At the meeting of the House of Delegates held on June 8th, Dr. Henry D. Holden of Brattleborough, Vermont, said that since the attention of the profession and the public had been drawn to the fact that the effects of venereal disease upon public health were comparable to those of alcoholism or tuberculosis, the national, State, and municipal authorities would be willing to coöperate in securing legislation for the prevention of the spread of this class of diseases. At present 33 States had no laws whatever on this subject except municipal ones. Michigan had a law forbidding the marriage of persons affected with this class of diseases and fixing a fine of from $500 (£100) to $1000 (£200) for its violation. The influence of the association in assisting the study of venereal diseases and in securing legislation for the prevention of their dissemination was urged.—At the general session of the association, the first meeting of which took place on June 7th, one of the most interesting subjects of discussion was the proposed memorial to the late Major Walter Reed who discovered that a mosquito conveyed yellow fever to man. Dr. W. W. Keen of Philadelphia informed the association that the committee of which he was chairman had been incorporated in the District of Columbia and was thoroughly equipped to take care of any funds for the purpose of raising a memorial to Major Walter Reed. He proposed that the association should contribute $10,000 (£2000) for the purpose.—Dr. William Welsh of Baltimore made an eloquent speech in support of Dr. Keen's motion.—The California State Society subscribed $500 (£100) to the fund and a number of physicians subscribed $1000 (£200) so that at the close of the meeting Dr. Keen was able to announce that $7500 (£1500) had been subscribed.—Dr. John H. Musser of Philadelphia was then introduced as president-elect and delivered an oration on Some Aspects of Medical Education.—The oration on medicine was made by Dr. George Dock, Ann Arbor, Michigan, after which a symposium was held for a discussion on Institutions doing Research Work for the Science of Medicine.

University of New York Medical College.

At a special meeting of the council of the University of New York held recently it was determined to purchase land adjoining the new college building and to proceed at once with the erection of a six-storey building for the clinics and laboratories of the medical college. Plans were submitted and approved and a building committee was appointed. The proposed building will adjoin at the rear the Carnegie laboratory which is a part of the University.

The Proposed Abolition of Coroners in New York.

There was general satisfaction both in lay and medical circles when a Bill for the abolition of coroners in New York city passed through the State legislature,[1] but the rejoicing was decidedly premature, for the Mayor has now vetoed the Bill.

Exclusion of Objectionable Advertisements from the Mails.

The Post Office Department of the General Government has taken a most important step towards the suppression of quack advertising. Those advertisements which are decided to be offensive in their character will be excluded for violation of the law as regards decency and those which advertise "fake preparations" will be excluded on the ground of fraud on the public. The plan of procedure will be to refer all drugs and nostrums to the Department of Agriculture for analysis to determine the sincerity of their claims as medicines and the facts of the analysis will then be referred to the Law Department for final action. It has been held by the law authority that any contract for advertisements of such objectionable matters is void when the Post Office Department has decided adversely on the character of the advertisement. The Postmaster-General states that the question of admission to the mails of newspapers containing advertisements treating of "private" diseases and offering for sale medicines designed for unlawful purposes has already been considered and it has been decided that such advertisements are forbidden circulation in the mails by the Act of Congress which declares to be unmailable any print or other publication of an indecent character and every article or thing designed or intended for the prevention of conception. On presentation to the department of any advertisement such as described the same will be duly considered and appropriate action taken.

Reciprocity among Examining and Licensing Medical Boards.

Most of the States have licensing medical boards befor which every intending practitioner must appear and pass an examination and show his diploma before he can be registered as a qualified physician. But these laws differ in different States and an association has been formed for the purpose of securing reciprocal relations between the board of the States and thus avoiding the necessity of repeating the examination when a physician removes from one State to another. At a recent meeting of the association a basis for reciprocal registration was presented under which the association or confederation is now working. This agreement recommends that there shall be uniform entrance requirements in all of the medical colleges, uniform standard curricula, and uniformity in the State board examinations for licentiates, with such additions as each board may see fit to make. Committees were appointed to confer with other bodies in regard to the plan proposed and to report at the next meeting to be held in October.

June 24th.

Obituary.

ALEXANDER OBERLIN MACKELLAR, M.D. R.U.I., F.R.C.S. ENG.,

SURGEON-IN-CHIEF TO THE METROPOLITAN POLICE.

FEW of the older generation of civilian practitioners have had more experience of the surgery of the battle-field than had Alexander Oberlin Mackellar whose death, as already announced in our columns, took place on June 15th at Bella Vista, Royston Park, Pinner, near London. He was born on Dec. 29th, 1845, at New Amsterdam, Berbice, British Guiana, where his father, who was a missionary, died from yellow fever in the previous August. At the age of six months he was brought to England and lived with an uncle until, when about ten years of age, he was sent to Silcoats school. His medical education was received chiefly at the Owens College and the Royal Infirmary, Manchester, and at Queen's College, Belfast. He also attended medical classes at University College, London, and in Paris. In 1869 he graduated as M.D. and M.Ch. at the Royal University of Ireland and in 1873 he was admitted F.R.C.S. Eng. He served in the Franco-Prussian campaign of 1870-71, for his work in connexion with which he was made a knight of the Military Order of Bavaria. Not long after his return to England he was appointed assistant surgeon to St. Thomas's Hospital but during great part of the years 1876 and 1877 he was in Eastern Europe, first as chief surgeon of the English ambulance in the Turko-Servian war, and secondly as consulting surgeon of the fifth ambulance of the Red Crescent in the Russo-Turkish war. For his work in these two campaigns he received decorations, being made a Knight Gold Cross of Takovo for the former and a Knight of the Order of Medjidieh for the latter. In 1885 he delivered the introductory address at the opening of the session at St. Thomas's Hospital; this address, an abstract of which appeared in THE LANCET of Oct. 10th, 1885, not unnaturally referred in very favourable terms to the opportunities presented by the medical service of the army. In 1886 Mr. Francis Mason died and the vacancy thus created was filled by the appointment of Mr. Mackellar as surgeon to the hospital Within a comparatively short time afterwards he succeeded Mr. Timothy Holmes in the office of surgeon-in-chief to the metropolitan police. This position is no sinecure and henceforth his energies were largely devoted to routine official work. Mr. Mackellar has left a widow for whom his numerous friends have expressed much sympathy in the loss which she has sustained.

One who knew him well in the days when he was on the staff of St. Thomas's Hospital has written to us as follows: "Mr. Mackellar joined the staff of St. Thomas's Hospital as resident assistant surgeon, coming from the Royal Free Hospital, where he had been senior house surgeon, with a reputation enhanced by the report of his services as an ambulance surgeon during the Franco-German war. Few of those who remember him at that time will ever forget the impression that he made, more especially on the students who came under his influence. 'Of good presence, with a ready and engaging manner, a fluent speaker, a good teacher and operator, his immediate acceptance as an acquisition to the hospital was assured and it was soon forgotten that he was not entirely a St. Thomas's man. He became assistant surgeon to the hospital and was granted leave of absence to serve with the Stafford House Committee's Ambul during the Turko-Servian campaign and during the f

---

[1] THE LANCET, May 7th (p. 1314) and May 14th (p. 1365), 1904.

Consequently the Local Government Board was unable to sanction the arrangement proposed in August, 1902. It is open to the guardians under Article 10 of the Dispensary Rules to appoint a small committee of its members for the purposes mentioned in the question. In the majority of the unions the guardians themselves examine the books. Elsewhere the duty has been delegated to a committee of guardians with satisfactory results.

Beri-beri in the Port of London.

Colonel Legge asked the Secretary of State for the Home Department whether his attention had been called to a statement made by Sir Patrick Manson in an address delivered at St. George's Hospital on Oct. 1st, 1897, that beri-beri was very common in the Port of London, especially among the Lascars and Seedy boys who in many instances formed the bulk of the crews of the large steamers trading to the East; whether he could state how many cases were treated annually at the Seamen's Hospital; and what precautions were taken to prevent the spread of the disease.—Mr. Long answered: My attention has been drawn to the statement referred to in the question. I am informed that the number of cases of beri-beri treated annually in the Seamen's Hospital in the ten years ended in 1900 averaged 24. The disease is not regarded by the medical officer of the Port of London as infectious in the ordinary sense and no special precautions are considered necessary.

Beri-beri in South Africa.

Major Seely asked the President of the Board of Trade whether he was aware that by the provisions of the Natal Act, Immigration (restricted), 1903, the master and owners of any vessel from which any person suffering from a loathsome or a dangerous contagious disease might be landed were liable to a penalty of from £100 to £5000; whether the master or owners of the British ship *Tweeddale*, from which immigrants suffering from beri-beri were landed at Durban, had been subjected to the penalties referred to; and whether he would take steps to warn the masters and owners of British ships of the penalties to which they were liable for any infringement of the provisions of the above Act while engaging in this traffic.—Mr. Lyttelton, who replied, said: I have telegraphed for information to the officer administering the Government of Natal and have received the following answer: "My Ministers suggest that you give following reply to question. It is the custom in Natal to subject persons to penalties after they have broken the law, not before. The *Tweeddale* did not infringe the Immigration Restriction Act. No British ships are liable to penalties for engaging in this traffic—namely, the conveyance of Chinese immigrants under a scheme approved by the Government of Natal. Both shipmasters and Transvaal Government have been duly informed of our law and of the requirements thereunder." It will be observed that the Natal authorities do not consider beri-beri to be a loathsome or dangerous contagious disease.

Tuesday, July 5th.

Distillation of English Spirit.

Mr. William M'Killop asked the Chancellor of the Exchequer whether he would state the total quantity of spirit distilled in England during the year 1903, and how much was used for methylation, rectifying, and compounding purposes; whether any English spirit was used as whisky in Customs warehouses in Leith, and, if so, what was the total quantity despatched thereto from distilleries in England; whether he had any official information showing the materials from which English spirit was usually distilled; and whether any beet molasses from abroad was used in its manufacture.—The Chancellor of the Exchequer answering said: The total quantity of spirits distilled in England during the year ended March 31st, 1904, was 11,694,851 proof gallons. The quantity of home-made spirits used for methylation during the same period was 4,398,002 proof gallons. I have no means of knowing the quantities used for rectifying and compounding. 33,300 proof gallons of British spirits were despatched to Customs warehouses at Leith from English distilleries during the 12 months ended June 30th, 1904. The materials commonly used in the distillation of English spirit are malt, unmalted grain, molasses, sugar, glucose, and rice. No doubt beet is used to some extent but I have no means of knowing the quantities.

Ankylostomiasis.

Mr. John Wilson (Durham) asked the Secretary of State for the Home Department whether he had taken or would take steps to insure that in the event of a case of miner's disease [illegible] arising in any coal or metalliferous mine a [illegible] be forthwith sent to the medical officer [illegible] inspector of the district in which such mine was situate and that the isolation of cases that might arise should be secured; and whether, if the administrative powers of the Home Office were not adequate for the purpose, he would introduce the necessary legislation.—Mr. Akers-Douglas replied: I have not yet learnt the results of the conferences between owners and men which were to be arranged in each district to discuss this subject generally and until I do so any statement as to the precise steps to be taken for the prevention of the disease would be premature, but I doubt whether from the nature of the case it is practicable to require notification and isolation of every case of the disease. I am glad to say that no case has yet been found in a coal mine.

The Production of Calf Lymph.

Mr. Field asked the President of the Local Government Board whether the Government hired live calves for the purposes of vaccinating for lymph, at what cost and how long those calves were kept, what became of them after being returned to the owner, whether this class of meat was sold as veal for public consumption, whether he had any reports on its fitness for human food by local medical officers of health, and whether it was identified when being sold as lymph veal.—Mr. Long replied as follows: Calves are hired at a cost of from 20*s.* to 25*s.* a week for the purpose mentioned. The number of calves used varies. At present the average number is approximately 15 weekly. The calves are kept for about two weeks. After the lymph has been collected from them they are slaughtered and their carcasses are thoroughly examined by a veterinary expert. Sound carcasses are delivered to the contractor by whom the animals are supplied to be disposed of as he think fits. The concern of the department in the matter then ceases. I am not aware that any medical officer of health has made a report on the subject but I am advised that when the carcasses are found to be sound there is no reason why they should not be sold for food. I have no information as to the practice with regard to the sale of carcasses as meat. The number of the carcasses delivered to the contractor in 1903–04 was about 1000. This is above the average.

BOOKS, ETC., RECEIVED.

Allan, T. and G., Newcastle-upon-Tyne.

Notes on Percentage Calculations, with Examples. By Frank R. Dudderidge, F.C.S., Pharmaceutical Chemist, Principal of the *North of England School of Chemistry and Pharmacy* (55, Northumberland-street, Newcastle-on-Tyne). Price 6*d.*

ONE SHILLING. R..........................

You are to attend your PHYSICIAN on MONDAY at 1.30 p.m., and THURSDAYS at 9.30 a.m.

Each Patient to bring a clean Bottle.

Take Notice, that if you neglect attending for Six Weeks the paper will be removed from your book. This card must be taken great care of and brought to the Hospital every visit.

THREEPENCE will be charged for each visit in the month.
(Available for one month only.)

Of A he says that the medical man who issued it received a reproof from the corporation to which he [illegible] ays that it can be obtained from the hospital [illegible] He asks us to indicate the difference betwe[illegible] cannot; but some of our readers might like to draw distinctions between the offer of cheap medical attendance when made by a practitioner and when made by a hospital.

F.R.C.S. EDIN. FOR PRACTITIONER OF TEN YEARS' STANDING.

A CORRESPONDENT writes: "I should be much obliged if any of your readers could give information about this examination—books to be read and which is the best optional subject."

HOLMAN TESTIMONIAL FUND.

THE following additional subscriptions to the above fund have been received:—

	£	s.	d.
Dr. E. C. Arnold	1	1	0
Mr. G. H. Barton	0	2	6
Dr. C. Dorrington Bath, J.P.	1	1	0
Mr. C. F. Wakefield ...	0	10	6
Mr. J. D. Malcolm	1	1	0
Dr. Bransby Roberts ...	1	0	0
Mr. E. Noble Smith ...	1	1	0
Mr. Alfred Winkfield ...	1	1	0
Mr. T. H. Martin	1	1	0
Mr. E. G. A. Walker ..	1	1	0
Dr. J. Hewetson	1	1	0
Dr. Clement Godson ...	1	1	0
Mr. C. T. Carnes	2	2	0
Balance at disposal of the South-East Branch of the British Medical Association, per Mr. T. J. Verrall	35	11	9
Dr. J. Mitchell Bruce ...	2	2	0
Dr. J. F. Goodhart ...	3	3	0
Sir John Puleston	2	0	0
Dr. R. M. Miller	1	1	0

The amount now subscribed is £422 16*s.* 9*d.* and an additional sum of £100 is required to carry out the proposed scheme of erecting an art and reading room at Epsom College. A further and, it is to be hoped, final list will be published in a month's time. Subscriptions of any amount will be received by Dr. John H. Galton, Chunam, Sylvan-road, Norwood, or by Mr. W. A. Berridge, Oakfield, Redhill, Surrey.

TAXATION OF CATS.

AT the last meeting of the Church Society for the Promotion of Kindness to Animals, held on July 1st at the Church House, Westminster, a paper was read by Mr. F. G. Aflalo on the Taxation of Cats. Mr. Aflalo advocated the imposition of a 2*s.* 6*d.* tax upon cats, advancing as reasons in support of his argument that a tax would raise the value of the animals and lead to their more humane treatment, while the revenue might be a considerable gainer thereby. The views of Mr. Aflalo received the endorsement of the meeting and for our part we agree with them. The rôle played by domestic animals in the propagation of disease is as yet ill-understood but cats of all domestic animals are the most nursed. They live in dangerous intimacy with many families and we welcome any departure likely to lead to the diminution of their number and to an increase in their individual value which will imply additional care as to their health.

THORNE DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—We beg to inclose a final list of subscriptions. The taxed costs, which are less than was originally expected, amount to £177 9*s.* 1*d.* This sum, added to the £25 damages which were awarded, brings the total expenses to £202 9*s.* 1*d.* The amount raised by subscriptions is £219 2*s.* It has been decided to divide the balance of £16 12*s.* 11*d.* equally between the New Hospital for Women and the Royal Free Hospital. It is hoped that this distribution of the surplus will meet with the general approval of the subscribers.

We are, Sirs, yours faithfully,
WALTER S. A. GRIFFITH, M.D. Cantab.
WALTER TATE, M.D. Lond.

◆

Sigma.—We do not think there is [illegible] t our correspondent's view, especially as [illegible] to be traced to meats which have not bee[illegible] there are no well-marked or outward signs of putrefactive processes having taken place.

R. S. F.—Salicyl sulphonic acid may be obtained from most dealers in chemical reagents. It is quoted in the list of Messrs Baird and Tatlock of 14, Cross street, Hatton-garden, London, E.C.

J. P. S.—We sympathise with our correspondent's view, speaking generally, but we do not think his letter has been aroused by any very glaring piece [illegible] snobbery.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any [illegible] to be connected with the [illegible] ecessary that attention be [illegible]

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

[illegible] insertion or for private informa- [illegible] d addresses of [illegible]

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1904, which was completed with the issue of June 25th, and the Title-page to the Volume, were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are;—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

METEOROLOGICAL READINGS.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France -J. ASTIER, 31, Rue Bapts, Asnières, Paris.

The Croonian Lectures

ON

BRIGHT'S DISEASE AND ITS VARIETIES.

Delivered before the Royal College of Physicians of London on June 7th, 9th, 14th, and 16th, 1904,

By JOHN ROSE BRADFORD, M.D., D.Sc. Lond., F.R.S.,

FEI [illegible] RINCIPLES AND [illegible] PHYSICIAN [illegible] DON.

LECTURE I.

Delivered on June 7th.

Physiological Considerations.

Mr. President and Gentlemen,—My first duty is to tender to you, Sir, and to the College my best thanks for the honour you have conferred on me in requesting me to deliver these lectures although I have many misgivings as to my capacity to deal adequately with the subject. The subject of Bright's disease is not only one peculiarly associated with English medicine and more especially with the names of Bright, Wilks, Roberts, Grainger Stewart, and many others, but it is also such a prevalent malady that I feel no apology is necessary for bringing it before you. Further, at the present time there is a great deal of confusion not only as to the fundamental problems connected with this disease, such as, for instance, its etiology, but also there is much diversity of opinion amongst different writers as to what renal affections should be included under the term Bright's disease.

The problem of the causation of disease is usually a far more complex one than the mere description of a malady. The fact that such widely differing conditions as amyloid degeneration, so-called chronic nephritis, granular kidney, and even such an affection [illegible] all be described by some und[illegible] is an index of the confusion [illegible] in this department of medicin[illegible] recognised by some that the term Bright's disease is no longer applied by them to a definite anatomical condition but is used much in the same way as the term diabetes is employed, or will be shortly—that is to say, as a symptom-complex or as the name connoting a number of symptoms or a certain clinical picture rather than a single morbid entity. Other writers consider the term Bright's disease and nephritis as interchangeable and talk of Bright's disease as chronic nephritis in one or another of its various forms. The number of affections of the kidney which may be included under the terms nephritis and Bright's disease is, however, so considerable that nothing is gained by including them all under one term either of nephritis or of Bright's disease. This is more especially true, not only on account of the mere number and variety of the different lesions, but also because they really differ very considerably in [illegible] sibly in their etiology. Quite ap[illegible] sentiment or those which us[illegible] in other branches of knowledge—viz., the priority of a given name—there are, in my opinion, sound reasons for maintaining the term Bright's disease. At the same time the group of cases to which this [illegible] ely limited one, characterised [illegible] y but more especially by the [illegible] the affection.

Bright's disease is usually looked upon as an affection of the kidneys, although perhaps it may be considered doubtful whether the lesion is one really limited to these organs. It has been rather too readily assumed that all the multifarious effects of Bright's disease on the circulation, such as the occurrence of dropsy and the [illegible] marked cardio-vascular lesions such as cardiac [illegible] and the well-known changes in the arteries, are e[illegible] explained as effects produced secondarily by an [illegible] lesion. To express it more accurately the view has been [illegible] on the disordered [illegible] not only been held [illegible] scular accompani[illegible] h reference to the nervous phenomena so common in Bright's disease. Although the details as to the nature of uræmia are not clearly understood nearly all writers on the subject consider the condition a toxic one and they associate the toxic state solely with the deficient excretory activity of the kidney. Thus it comes about that the widespread effects which we associate with Bright's disease, and especially with chronic Bright's disease, such as the dropsy, the cardio-vascular changes with all the evils that follow in their [illegible] ation the various secondary and [illegible] and all regarded as dependent [illegible] the excretory function of the kidneys. This is unquestionably one of the problems lying at the root of the pathology of Bright's disease and no doubt in a certain sense all these effects are due to the renal lesion, or perhaps it would be better to say are associated with some variety of renal lesion. But it is perhaps doubtful whether in the present state of our knowledge we are justified in looking upon all these widespread effects as a result of a cause or causes acting entirely on, and producing results only in, the kidneys.

A great many of the difficulties that have arisen in interpreting the phenomena of Bright's disease and other affections of the kidney have been due to a want of complete accord between the known facts as to the physiology of the kidneys and certain phenomena observed in disease of these organs. This has been especially the case in many of the discussions that have taken place with regard to the nature of uræmia. The same difficulties have also presented themselves in connexion with other phenomena of renal disease such as renal dropsy and the very extensive cardio-[illegible] many kidney diseases. Throughout [illegible] may be said that our knowledge [illegible] aries directly with the extent of our knowledge of the physiology of the organs concerned. [illegible] is done to the progress of [illegible] ansference of physiological [illegible] biology which is known as medicine. All the same advances are made through the intermediation of pathology. In some instances the first gleams of our knowledge of the physiology of certain organs have been derived from the study of clinical medicine but it is only when these have been extended and more accurately [illegible] y and later by [illegible] edicine has been [illegible] pendence of the three branches of knowledge, [illegible] medicine, is afforded by the hist[illegible] functions of the cerebral corte[illegible] localisation was obtained by the [illegible] Hughlings Jackson. The work of the physiologist added that definiteness which after all can only be obtained by the experimental method and at the present time the more or less minute and accurate knowledge that we possess of the functions of the cerebral cortex is at any rate very largely due to the work of the pure physiologist. The history of these discoveries, however, shows amongst other things the very great results that can be obtained from the study of medicine by the clinician with the aid of truly scientific methods.

Addison's disease may be quoted as an example of a malady where almost the whole of our knowledge is derived from the study of pathology and the unsatisfactory state of our knowledge as regards the nature of this disease may perhaps be said to be largely dependent on the want of full knowledge of the physiology of the suprarenals. The great discovery of the internal secretion of these organs elucidates, no doubt, part of the pathology of Addison's disease, but a part only, and until the physiology of the cortex of the organ is ascertained or possibly some hitherto unknown other function our knowledge of the pathology of Addison's disease will remain incomplete. Many other illustrations of the mutual interdependence of physiology, pathology, and medicine might be quoted but probably all will agree that where our knowledge of the physiology of an organ is scanty there also our conceptions of the diseases affecting the structure [illegible] certain, and it is owing to the numerous [illegible] in medicine that so many look upon [illegible] truly scientific study; that, however, [illegible] subject but on the bent and training of mind of those who pursue it.

In the case of renal diseases, and more especially perhaps in Bright's disease, as stated above, many of our uncertainties as to the interpretation of the phenomena seen in the course of disease depend very largely on some of the

in birds. It would not seem to be probable that a function which is discharged by the liver in one set of vertebrates, such as birds, would be discharged by another organ, such as the kidney, in another set of vertebrates, such as mammals, and therefore it is improbable that the kidney is the seat of the formation of uric acid in mammals and in man. Another reason, doubtless, that has led to the hypothesis of the formation of uric acid in the kidney is the fact that a somewhat allied body—hippuric acid—may unquestionably be formed, thanks to the activity of the renal protoplasm, so that it cannot be denied that apart from the true excretory function of the kidney this organ is capable of affecting syntheses, such as the union of benzoic acid with glycin. This action of the renal cells is, however, not limited to them and may also be effected by the protoplasm of other cells—e.g., the liver. It will thus be seen that there is really but little, if any, evidence in favour of the view of the kidney having a special secretory activity, although perhaps it would be unwise to deny the possibility of it. Many substances taken into the body, as, for instance, certain drugs like chloral and carbolic acid, are excreted in the urine in combination with complex acids like glycuronic acid and sulphuric acid. But there is no evidence that this union or conjugation takes place in the organ itself.

Another problem in relation to the physiology of the kidney which has a most important bearing on the pathology is the question as to whether the kidney is provided with an internal secretion, and the most divergent views have been held with regard to this. It may be said that the conception that the organ has an internal

the phenomena of acute uræmia as seen in the case of scarlatinal nephritis and the latent uræmia accompanying calculous obstruction are so great that it is not surprising that many observers have thought that the explanation of these differences is to be found in the hypothesis of an internal renal secretion. In the scarlatinal nephritis or other destructive disease of the kidneys both of the supposed functions of the organ would be arrested, whereas in calculous or other forms of obstruction only the external secretion or excretion. This doubtless might be a ready and simple explanation of the supposed facts. Additional evidence in support of the same view was supposed to be afforded by the earlier experiments of the results following double nephrectomy on the one hand or ligature of both ureters on the other in animals. Speaking broadly, the effects of double nephrectomy were more violent and more rapid in their course than those seen after ligature of both ureters and it was supposed that owing to the severity of the vomiting in the first group of cases there was a greater resemblance to uræmia as seen in the human subject.

The question of the existence or non-existence of an internal secretion is one that must be determined solely by physiological methods and before its existence can be admitted the same kind of evidence must be available in the case of the kidney as in the case of other glands. This evidence may be said to consist usually of three parts. In the first place a gland that is provided with an internal secretion usually presents distinct histological evidence in support of the existence of this function. Thus in the case of the thyroid not only can the colloid material actually be seen
organ but in addition the
own parathyroid tissue are
the gland. In the case of the pancreas certain definite structures known as the islands of Langerhans are found in the substance of the gland, although it must be admitted in the light of Dale's observations that possibly the connexion of these cells with the internal secretion of the organ is not so direct as has been supposed. In the case of the liver, although there may not be histological evidence in the ordinary sense of the word, yet the staining of the organ reveals the presence of glycogen in its substance. In the second place, where an internal secretion is unquestionably present the results of removal of the gland in question are different from those seen from the mere ligature of its duct where the gland is one provided with a duct. This is notably the case with the liver, the pancreas, and the testis. In all these three instances there is no sort of resemblance between the phenomena produced by ligature of the duct and those produced by extirpation of the organ. In the third place an extract can usually be obtained from glands possessing an internal secretion which frequently contains certain definite chemical substances and which may have very marked physiological and even th
the
case of the liver, th
stis
substances can be
rac-
teristics and, as is
and
the suprarenal at an
nite
physiological but
It
is true that in son
era-
peutic action and even the nature of the substances are not thoroughly known and this, perhaps, is especially the case with the pancreas and the testes, but the phenomena following the excision of the gland are so strikingly different from those seen after ligature of the duct that no doubt can be entertained of the real existence of an internal secretion.

When we turn to the kidney the facts obtained by experiment are very different and present considerable difficulties in their interpretation. If the organs are removed by the modern methods of aseptic surgery, and especially if the two kidneys are not removed at one operation but one after the other with a considerable interval, the effects produced are very different from those seen by the earlier experimenters and in my opinion no marked distinction can be drawn either as regards the duration of life or as regards the symptoms produced by double nephrectomy on the one hand or by ligature of both ureters on the other, or by nephrectomy on one side and ligature of the ureter of the remaining kidney. In all these conditions the most marked effects produced by the operation are a progressive weakness, refusal of food, a great fall in body temperature, some dyspnœa, diarrhœa, great wasting, occasional vomiting (this last symptom sometimes is absent), and death usually occurs on the fourth day. In the course of many experiments I have never seen any clinical symptoms presenting any close resemblance to those seen in acute uræmia in man, such symptoms, for instance, as severe vomiting, convulsions, or coma. It might, perhaps, be further added that the same train of symptoms is also seen where the functions of the kidney are arrested by ligature of the vessels in the hilum. Two deductions of some importance are to be drawn from the results of such experiments. In the first place, the symptoms and mode of death are similar, whether the functions of the kidney be arrested by double excision, by double ligature of the arteries, or by obstruction of both ureters. Secondly, these symptoms and the mode of death present a greater resemblance to those described in the human subject as latent uræmia than to those described as ordinary uræmia complicating acute or chronic renal disease.

The structure of the kidney does not yield any evidence of the existence of any groups of cells that might be supposed to yield an internal secretion, such as are found, for instance, in the pancreas or in the testes. At the same time this is, perhaps, not an argument of much weight because the liver undoubtedly is provided with an elaborate internal secretion, but yet this could scarcely be deduced from the histology of that organ. The most convincing evidence in favour of the existence of an internal secretion has in many instances been afforded by obtaining an active extract from the gland in question, so that the results of experiment with renal extract are those to which we would perhaps turn in order to clear up the difficulty as to the existence or non-existence of an internal secretion. Unfortunately, the evidence under this head is of an inconclusive character, different observers having obtained discordant results. Brown-Séquard, as is well known, was of opinion that most of the glands of the body possess internal secretions and in 1889 he advanced the view that the kidney was provided with an internal secretion
nomena of uræmia was
d this view not only on
the supposed beneficial
influence of renal extracts in the treatment of the so-called experimental uræmia and also of the ordinary uræmia seen in renal disease. Brown-Séquard's experiments were performed on nephrectomised rabbits and guinea-pigs and he stated that as a result of treating these with renal extract the period of survival was slightly longer than in the controls. Meyer in 1894 repeated these experiments, experimenting both on dogs and on rabbits, and he used a glycerine extract of the kidney of the dog for the purposes of treatment. Meyer found that after double nephrectomy Cheyne-Stokes respiration became developed in some 36 hours and he stated that the injection of some 20 cubic

centimetres of the renal extract caused the subsidence of the Cheyne-Stokes breathing, at any rate temporarily. He did not, however, obtain any very marked prolongation of life. Meyer also observed that venesection after double nephrectomy, followed by the transfusion of small quantities of defibrinated blood, also led to the disappearance of the Cheyne-Stokes rhythm. In a further series of experiments, instead of transfusion with ordinary defibrinated blood, he used defibrinated blood obtained from the renal vein and he stated that the improvement or temporary subsidence in the symptoms was in these circumstances of a more prolonged character. Meyer finally concluded that the blood of the renal vein contains some material elaborated by the kidney and capable of exercising a beneficial influence on the toxic state produced as a result of double nephrectomy. Vitzow performed somewhat similar experiments in dogs and rabbits and he also claimed that the injection of blood from the renal vein of healthy animals led to the prolongation of life in the nephrectomised animals. Two Italian observers, Ajallo and Parascandallo, were also of opinion that the injections of renal extract after double nephrectomy caused some prolongation of life. Tiderstedt and Bergmann adduced some experimental evidence to show that the extract of the cortical substance of the kidney had a vaso-constrictor action on the blood-vessels. This observation was contradicted by Lavandowski, inasmuch as he failed to obtain any effect on the circulation with the injection of renal extract and he came to the conclusion that an internal secretion did not exist. Dieulafoy, Tessier, Frankel, and many others have recorded cases in which the injection of renal extract in the human subject in cases of uræmia has been followed by a considerable increase in the flow of urine, together with a subsidence of the uræmic symptoms. De Lignerolles has used a serum obtained from the renal vein of goats in doses of some 20 cubic centimetres in the treatment of four cases of uræmia in the human subject and he states that in three cases there was very considerable improvement not only in the general condition of the patient but that the improvement was also shown by a diminution both of the toxicity of the urine and also of the amount of the albuminuria. Chatin and Guinard, in reviewing the literature in 1900, considered that on the whole there was definite clinical evidence of the beneficial effects of the treatment of uræmia by renal extract, although they acknowledge the very numerous sources of error owing to the great and sudden improvement that may ensue in uræmia as a result of other methods of treatment.

It is, of course, obvious that the treatment of uræmia by renal extract, even if the kidney possesses an internal secretion, cannot possibly meet with the same measure of success as is the case in the treatment of myxœdema with thyroid extract, inasmuch as the thyroid is not known to possess any other function, whereas in the case of the kidney it is impossible for life to be maintained when the excretory function is abrogated or seriously impaired. Stern, in 1903, reinvestigated the whole subject and made a complete series of observations on a large number of animals. In his first series of observations nephrectomy was done in two stages and the animals were treated with subcutaneous injections of a watery renal extract. Such animals, however, did not survive longer than the controls. In the second series the ureters were ligatured in place of the kidney being excised and here his results coincide with mine inasmuch as he found that the period of survival was no longer than in the controls in which double nephrectomy had been performed provided that the double nephrectomy was performed in two stages in order to eliminate shock as much as possible. In a further series of observations Stern injected an indifferent fluid, such as 0·8 per cent. of sodium chloride, after double nephrectomy, and in order further to control these results he injected in a certain number of control animals equivalent quantities of renal extract. As a general result of his observations he found that the animals treated with physiological salt solution might survive for considerably longer periods than those simply nephrectomised. A rather remarkable observation was the fact that in many instances more prolonged survival was seen in the animals that received the largest injections. Stern considers that dogs do not as a rule survive double nephrectomy more than 70 hours, but if treated with large quantities of physiological salt solution the survival may be prolonged to 90 or even 132 hours. He further draws attention to the fact that where vomiting and diarrhœa are marked symptoms the duration of life is more prolonged. Stern considers that his experiments do not afford any evidence in support of the existence of an internal secretion and that the variability in the duration of life after double nephrectomy depends to a certain extent on the variable degree of resistance of individual animals to toxic agents and that the beneficial effects of the injection of salt solution are probably merely dependent on the dilution of the toxic materials in the blood and possibly to their elimination by other channels and more especially the bowel. Stern's results are not only of theoretical interest but it is possible that the injection of large quantities of saline solution might be of use to prolong life in some forms of uræmia where there is a possibility of the renal functions becoming re-established. It has long been known in medicine that temporary improvement in the uræmic state might be induced as a result of venesection followed by transfusion. It is possible, however, that beneficial results on the lines of Stern's experiments might be obtained in cases of latent uræmia associated with complete suppression, calculous or other, where the prolongation of life by means of these injections might turn the scale in favour of the patient.

It will be seen that there is really at the present time no conclusive evidence in support of the existence of an internal renal secretion. On the other hand, the results I brought before the College in 1898 in the Goulstonian lectures show that there is some obscurity as regards the functions of the kidney, as it is impossible to explain the general disturbance of nutrition accompanied by marked wasting and the notable increase in the excretion of urea seen after removal of portions of the kidney as simply dependent on some deficiency in its excretory activity. These observations showed that the formation and excretion of urea were certainly controlled in some way by the amount of kidney substance present inasmuch as animals possessing one-third of their initial kidney weight were capable of living for indefinite periods, showing no other symptom of disorder than an increase in the amount of urinary water, whereas when but one-fourth remained death occurred associated with an increased excretion of urea together with great wasting. There is unfortunately no further evidence to explain the mode of production of this metabolic disturbance.

In concluding a review of the physiology of the kidney in so far as it affects the study of pathology and medicine it will be convenient to emphasise the similarity that really exists between the experimental results and those seen in the human subject as a result of disease. The fact that suppression of the functions of the healthy kidneys in animals is not really followed by the development of ordinary uræmia is one that I have not only emphasised in these lectures but also [illegible] of the renal arteries, double nephrectomy, [illegible] both ureters, although diverse proceedings, are all followed by the same result and produce, as mentioned above, symptoms which are more comparable to those seen in calculous obstruction and described as latent uræmia in the human subject than to the acute uræmia seen in other renal diseases. The view has, however, been held in human medicine that this clinical picture known as latent uræmia is characteristic specially of calculous obstruction. I would, however, urge that this is not really the case and it is simply that calculous anuria is the most common condition in which it is seen owing to the frequency of this malady and a precisely similar clinical picture is seen in quite a number of other renal conditions. Thus there are obscure conditions where the excretory function of the kidney is entirely arrested as a result of some supposed reflex irritation, and one such case I recorded in my Goulstonian lectures where complete suppression ensued as a sequel of a peculiar form of gangrenous cystitis and yet where there was no obvious disease of the kidney to account for the complete suppression. This patient presented symptoms precisely similar to those seen in ordinary complete calculous anuria. Thirdly, obstruction of the renal arteries, doubtless a very rare condition, an instance of which was recorded by Mr. Lawrence and myself, again produced the same clinical symptoms. Fourthly, somewhat analogous symptoms associated with complete suppression may occasionally be seen in diphtheria but here vomiting is, perhaps, more apt to be present and in some instances, owing to the production of well-marked renal disease, the effects are more comparable to those of ordinary uræmia. Lastly, I have recently, through the courtesy of my colleague, Mr. Godlee, had an opportunity of seeing the specimens from a case where the symptoms presented were again those characteristic of calculous obstruction but where the lesion was an acute hæmorrhagic nephritis. The consideration of all the experimental and these pathological results, I think, justifies the conclusion that the suppression of the functions of the healthy kidneys in man or in animals produces a set of symptoms that should be spoken of as those of latent uræmia and not those of ordinary acute, subacute, or chronic uræmia.

A Clinical Lecture

ON

REMISSIONS AND RELAPSES IN INSULAR SCLEROSIS.

Delivered in the National Hospital for the Paralysed and Epileptic, Queen Square, on Feb 9th, 1904

BY THOMAS BUZZARD, M D, F R C P LOND,
CONSULTING PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—IT is known that in a very considerable proportion of cases the course of insular sclerosis is marked by more or less frequent remissions and recurrences of symptoms. The fact was recognised by Charcot and has been mentioned also by succeeding writers, but to my mind sufficient prominence has very seldom been given to this interesting and exceptional feature of the disease. It has appeared to me worth while, therefore, to devote a lecture to the subject and thereby perhaps to aid in drawing more particular attention to a peculiarity of the disease which may be found to bear with some importance upon its diagnosis and it is conceivable also upon the question of its etiology. This feature is illustrated by the case of a female patient in attendance.

The patient is a married woman, aged 36 years who was admitted into the hospital under my care in September, 1900, complaining of loss of power in the left leg weakness across the loins, a general feeling of weakness, numbness of the fingers of the left hand and weakness of the bladder. Such were the symptoms which she herself described. Others were brought out upon examination, and we shall come to them presently. She said that her illness had lasted about 18 months, but on further questioning her it appeared that this short period by no means really represented the duration of her disorder. 12 years previously, in September 1888, one year before her marriage, she had complained of numbness in the soles of the feet which 'felt as if they were asleep.' This lasted for a week and then passed off entirely. In September, 1889 about the time of her marriage, numbness in the feet recurred and this time it extended to the calves of the legs and lasted for about three weeks. Again it passed away completely. In Augus
first time she again suffere
extended from the knees to
time she had double vision
side of the face, described by her medical adviser as Bell's paralysis. These symptoms lasted about a month and then quite cleared off under treatment. In 189 just as she was pregnant for the second time she again had an exactly similar attack upon the left side of the face, which also lasted for a month. About the same time she likewise noticed some numbness in the fingers of both hands. This has never quite left her since but has varied in degree from time to time. With the exception of this numbness which was so slight as to cause her no practical inconvenience and indeed scarcely to attract her attention, she remained completely well till December 1895, a period of some three years. She was then confined for the third time and three or four months later had to seek medical assistance on account of numbness and loss of feeling in the hands and arms so that "she could not sew or peel potatoes." She also had some loss of power in the left knee and for two months was unable to walk. After being away in the country for a time she became practically well again in all respects. And so she remained until April, 1899, when, being again pregnant, she complained of heaviness in the legs and some weakness across the back but no numbness on this occasion. The child, a healthy one, was born in September but after her confinement she continued to become weaker and to complain of a 'heavy pain' across the loins. At the same time she first began to notice some precipitancy of micturition. In 1900 her walking power diminished and she fell and was unable to draw up her left leg, the ankle and knee being stiff, and on admission here she could not walk without assistance. The bladder trouble, too had been worse and there had been occasional incontinence of urine. There had been no further diplopia. The following note refers to her condition in November, 1901 when she was shown by me at a lecture in this theatre. The patient is well nourished, of placid, easy going disposition, cheerful, but not especially emotional. *The bright but rather vacant expression is very suggestive of* that which is so often noticed in cases of insular sclerosis, but mentally she is intelligent, with good power of memory and attention. There is no articulatory difficulty. The ocular movements are good, but extreme lateral rotation is not well sustained to her right and when the eyes are turned to her left a few slow jerking movements are remarked, of a nystagmoid character. The jaw movements are equal and powerful on the two sides. There is no affection of sensibility in the face. There is no abnormality in the districts of the ninth tenth and twelfth nerves. In the upper extremities we find all movements powerfully performed and it may be said that there is no marked intention tremor but when by request she touches the tip of her nose it is noticed that there is a slight wavy motion of the finger as it nears the face. In the lower extremities we find on the right side all movements present and power good. There is a little incoordination but no rigidity. On the left side the muscles are equally well developed but their power is much less and there is a great deal of spasticity. Dorsiflexion of the ankle is practically absent. Her gait is spastic especially in the left leg, which is moved much like a hemiplegic limb. There are subjective numbness in the fingers, especially of the left hand, heaviness and dull pain across the loins but no definite girdle sensation. Objectively there is no change to tactile stimulus. There is marked loss of sensibility to pain in the left leg as compared with the right not quite constant, and extending from the foot (not including the sole) to above the knee without any definite limits. As regards reflex movements there is brisk jaw jerk, the supinator jerk is in excess on the right side the triceps jerk excessive on the right, absent on the left. The knee jerks are both equally in excess and ankle clonus is present on each side. The plantar reflexes are both brisk and show extensor (Babinski) response. There is precipitate micturition with occasional incontinence of urine. Examination with the ophthalmoscope shows both discs rather pale especially in the temporal half of each and the left is more pale than the right, the vessels are of good size. The field of vision both to colours and light *is somewhat restricted concentrically in the left eye*.

The patient for the last two years has been at home but attends to-day at my request. Her walking power since the above note was taken has much diminished and there is now some spasticity in the right lower extremity as well as in the left.

I have entered into what is perhaps a somewhat wearisome detail of this case because it is one which manifestly strays from the commonly recognised type of insular sclerosis. Yet it is clear that this affords the only reasonable solution of the symptoms shown in the patient's history and present condition. In no other way can we explain the presence of such symptoms as transitory numbness, diplopia, short lived but recurrent facial paralysis loss of power with spasticity of gait, ankle clonus the Babinski phenomenon, and pallor of the optic discs. This then is a case of insular sclerosis which well illustrates the importance of recoveries and relapses as a symptom of the disease. There is no doubt that not only have recoveries such as have occurred here been in many cases the cause of a patient's illness being lightly treated as one of hysteria but also in my judgment, the common picture of hysteria has been somewhat largely based upon a misinterpretation of such symptoms.

Another example is that of a man aged 35 years tailor married who was first admitted under my care in April 1895 with not strongly marked symptoms of insular sclerosis. It seemed that in 1881, when 21 years of age he suffered from some hemianæsthesia from which he rapidly and completely recovered and remained well till 1894. He then complained of numbness tingling, and weakness in both hands and feet

From this he recovered in a fortnight and returned to his work. About a year later he was again attacked with numbness in both feet and slightly in the hands, together with some weakness in both lower limbs, especially the right. There was also some slight bladder trouble. He had to give up work and was eventually admitted into this hospital. He had then distinct weakness in the right upper and slightly also in the right lower limb. There was loss of sensation, both to touch and pain, in front of each thigh. The knee-jerks were in excess. After a few weeks he had improved and was able to leave the hospital, walking alone. After his discharge he continued to improve and was apparently quite well in a month or two. He remained well and steadily at his work for nearly three years. In 1898 he began to be weak in the legs again but remained at work till June, 1900. He was then much worse and could not walk without help but after three weeks' stay in a convalescent home he improved greatly and returned home, but still continued to suffer from numbness and stiffness of the fingers which interfered with his work. He again became worse and was readmitted into this hospital in January, 1901. I will only refer to a few salient points of his condition at that time. There was a little "intention" tremor in the arms, especially on the right side, and he was clumsy in both hands in picking up a pin. The right leg was weaker than the left, especially in dorsiflexion of the foot, and there was some rigidity on both sides, with incoördination of the right foot. His gait, too, was unsteady and of the spastic-ataxic type. The wrist and knee jerks were in excess, but there was no ankle clonus. The plantar reflexes were brisk, with extensor (Babinski) response. Patches of anæsthesia were found about his trunk and legs. This patient steadily improved in hospital at first, and the anæsthesia practically disappeared. After being discharged he again had a relapse and was unable to walk. There were marked increase in the spasticity of his legs and some return of anæsthesia. After keeping in bed for a short time he improved, but still showed an ataxic gait with some spasticity. He was discharged in May, 1901. At the present time he is under treatment in another hospital. On inquiry I have ascertained that he cannot stand without support or guide his hands. Work has been impracticable for four years past. (By the courtesy of hospital colleagues other cases illustrating the subject were shown.)

It is evident that the extreme irregularity which characterises the distribution of the patches of sclerosis in different examples of the disease under consideration makes it quite unreasonable to expect the same degree of uniformity in the symptoms that we are accustomed to find when sclerosis is of the "system" type, as, e.g., in tabes. It is by comparison of numerous examples, some of them verified by post-mortem examination, as well as by consideration of the effect which a sclerotic patch will be liable to produce when occupying any particular locality, that the ability to classify such cases as these under the name "insular sclerosis" is attained. The "symptom-complex"—to employ the rather unwieldy expression borrowed from the German—or "syndrome," to use the term employed by the French—the peculiar aggregation, that is, of the symptoms, points, I think, conclusively to this explanation of the cases.

In the course of private practice I have met with many examples—some of which have been already published[1]—of the tendency to remissions and relapses in insular sclerosis. Let me refer, though very briefly, to a few more of these, because in a subject of this kind a description of incidents occurring in concrete examples is more striking than any abstract statements.

CASE 1.—A woman, aged 33 years, whom I saw about a month ago, had an attack of influenza in 1895. Shortly afterwards she squinted and lost the use of her right hand and arm—i.e., although able to move it she could not use it for lifting things or dressing. She also lost feeling in it. At that time she dragged one of her feet, although she was not conscious of loss of power in it. The trouble in her limbs described lasted for about a month and then improved, although she did not quite regain the power. She had been very much improved for about a month when she relapsed and this time both right arm and leg were affected. For three weeks she was very helpless and stayed in bed for the most part. She then began to improve and perfectly recovered in the course of some months. From that time (between seven and eight years ago) she remained perfectly well until June, 1902, when, as she describes it, the right arm began to be weak and the weakness spread to the right hand. Just as happened before, she again became practically helpless in this limb and the leg was also affected to a certain extent. She went to the seaside and after a month had quite recovered. She remained well for a month and then felt her leg losing power again, and although keeping about she had great difficulty in walking. The right arm, too, was slightly weaker but she was able to use it. On the first attack eight years ago there was some difficulty in restraining the action of the bladder and this difficulty recurred in the last attack. There is now some weakness of the right limbs with attempted ankle clonus. On the occasion of my examination I failed to elicit any plantar reflex.

CASE 2.—A woman, now (1904) aged 48 years, lost the sight of her right eye in less than a week when 23 years old. At its worst she could not perceive light. It gradually recovered completely. A few years later she had transitory tingling in the right arm and weakness in one ankle, which passed off. About 1894 there were loss of power to hold a pencil and dragging of the right leg, from which she also recovered. I saw her in 1898 when the right leg was very useless and she could only walk with help on each side. In reply to my recent inquiry her medical attendant reports the legs spastically paralysed, especially the right, presence of the Babinski phenomenon, and very feeble grasp of the hands.

CASE 3.—A woman, aged 22 years, was in excellent health till February, 1899, when vision with the left eye became indistinct and she had headache and giddiness. The left hand and arm were numbed and she could not walk properly, the right leg especially being weak. In April, 1899, an ophthalmic authority found vision on the right side $\frac{6}{6}$, on the left $\frac{6}{60}$, both eyes emmetropic, and the fundi normal. The diagnosis given was "functional derangement of nerves at the back of the eye." In April, 1900, I found right vision = $\frac{6}{6}$, left vision = $\frac{6}{6}$. The fundi were normal. There was nystagmus. She complained of "pins and needles" and numbness in both hands and below the left knee; she could walk a mile but would then be tired. There had been inability to hold a pen but she could now write. The plantar reflexes showed extension (Babinski) movement. I thought that she had suffered from retro-ocular neuritis in the course of insular sclerosis. Under observation in London she greatly recovered her health and her medical attendant wrote me a year or more later, "I am glad to tell you that she is doing well, hunting, and driving about in her old dashing style, and they speak of her as being 'quite well now.'" A few days ago I heard that she had had no return of the numbness or loss of power in her limbs, and that she was able to take riding, driving, and walking exercise, though in riding she had not regained the full grip of the saddle. It is, I suppose, possible that there may be no new developments in this case, but in view of what so commonly happens one cannot be at all free from apprehension that a relapse may some day occur.[2]

CASE 4.—A woman, in 1894, suffered from weakness and tremor in her legs, for which she had to keep her bed for some days. From this she recovered perfectly and remained well till 1897, when she began to lose strength in her legs and fell on several occasions. Four months later I found some spastic paraplegia, weakness of the sphincters, excessive knee-jerks, ankle clonus, and pallor of the left optic disc. The vision = $\frac{6}{12}$; there was some intention tremor of the hands.

CASE 5.—A woman, aged 31 years, whom I saw in 1901, suffered from an illness at 13 years of age, in which she had double vision and squinting, and staggered in walking. After two or three months she quite recovered, Three years later the sight of the left eye became bad and an ophthalmic authority who examined her is said to have expected that she would become blind, but great improvement occurred and the vision with that eye I found to be g though the disc was distinctly atrophic Diplopia had since occurred for several weeks at a time on three different occasions A few years ago however she was so well that she walked ten hours a day in Switzerland After this there was for a time some loss of power in the right leg More recently the left leg became weak and still remained so when I saw her She presented besides the eye symptoms mentioned a characteristic staggering gait, excessive knee jerks extension (Babinski) movement in the plantar reflex on both *sides and slight nystagmiform jerking At times she had* had numbness in her hands with *inability to use them* properly but that was not now the case Some time after my examination I learned that she had again recovered her health and had married I am unable to report her present condition

---

[1] Simulation of Hysteria by Organic Disease of the Nervous System. Churchill, 1891. Clinical Lecture on Insular Sclerosis and Hysteria. THE LANCET, Jan. 2nd, 1897, p. 1.

[2] Since this lecture was sent to press I have had the opportunity of once more seeing this patient. She looks the picture of health, and is studying in a school of art. On examination I note the following. Her upper extremities are absolutely right; there is no numbness or "pins and needles" in them, and she is able to draw with a perfectly steady hand. If she walks much the "*feeling seems to go in her left knee and leg.*" Two years ago she could dance well but of late this has been quite impossible, owing to extreme giddiness. Holding the head down causes giddiness. During last winter she hunted, but owing to her want of grip, especially with the left leg, in jumping she *had to rely very much upon her balance instead of depending upon the* crutch. The plantar reflexes are of the extensor (Babinski) type. During the last year or so there has been a return of the visual difficulty which, according to her account, had entirely subsided and I now find V. R. = $\frac{6}{5}$, L. = $\frac{6}{24}$ with paracentral scotoma. She has no diplopia. Both discs are pale in the outer part, especially the left.

CASE 6—A woman aged 36 years was sent to me in April, 1899 suffering from loss of power in both legs, back hands and arms a *staggering gait*, and *stiffness* from the hip to the knee The knee jerks were excessive ankle clonus was present on each side with marked extension (Babinski) response in the plantar reflex There was nystagmus and also atrophy of the left optic disc The history was that she had been particularly healthy and exceptionally strong muscularly until 1890, when she suffered from two attacks of influenza After being in bed for ten days in the second attack there was some loss of power and sensation in her legs After this although she recovered her general health completely *she thought that she never seemed to regain the* spring' in her walk but at times she was *so much improved as to* be unconscious of anything being wrong After this there appear to have been several relapses and remissions At one time there was involuntary escape of urine and fæces but this passed off in six weeks For one and a half years she had complained of diminished sight of the left eye and latterly that of the right had not been strong During the nine years of illness her case had been always diagnosed as one of hysteria except by the last medical man consulted who recognised its nature and sent her to me In 1901 I *received from him the following in reply to my inquiry as to* the sequel of the case The mother was so annoyed at me for saying it was not hysteria and at you for supporting me that she removed the case out of my hands I have made inquiries among some of the relatives but can get no information except that the symptoms had slowly increased and she died of exhaustion about 15 months ago

Here I am tempted to quote from some notes of a case which I took in May 1868 at a time when this disease had been I think scarcely differentiated and when certainly I knew nothing about it

CASE 7—The *patient a man aged 41 years had never had* syphilis or any severe illness or trauma 23 years ago he found himself one day lame in the left leg with twitchings in it and a feeling as though it were asleep In a fortnight he was quite well and remained so for three or four years Then he had a second attack like the first which lasted also about a fortnight when he returned to business A few years later he had another attack of similar character and has never since quite regained the power of the left leg Two years previously he felt some numbness of the left hand He has never had pain in the leg but of late a little walking even for half a *mile would exhaust him utterly* A few days previously he felt for the first time powerlessness in the right leg with numbness There was also diminished grasp of the right hand and for several days he had headache and lost power rapidly in his limbs and back For the last few days he had been getting better again In the morning his left leg was stretched out and he could not bend it The grasp of the right hand was fair, that of the left was [illegible] es failed to lift the [illegible] sed them to act fier [illegible] exalted (The Babinski phenomenon was evidently present) Sight had been hazy during the last few months The expelling power of the bladder was not great and he could not hold his urine to a great extent I do not know the sequel of this case which was evidently, however *one of the class* which we are considering

CASE 8—To complete the picture let me now quote notes of a case which was under my care in this hospital many years ago the diagnosis of which was confirmed by necropsy In May, 1885 a female, aged 27 years previously in perfect health, fell upon her hands whilst *running and* rose with great difficulty on account of extreme giddiness which had doubtless occasioned her fall In a few minutes she recovered and for a week had nothing to complain of then her sight became indistinct she had diplopia and pain at the top of the head She attended here as an out patient and gradually lost her symptoms In February 1886 she was suddenly unable to walk and lost power also in her arms Two months later she could not stand There were difficulty in micturition and occasional leakage of the bladder Admitted as an in patient in July, *1886 she lay in bed with but little power of moving her* limbs *There was some anæsthesia of the lower extremities* The knee jerks and plantar reflexes were present, there was no ankle clonus Later she suffered from spastic rigidity of the legs marked interosseal muscular atrophy of the hands, absence of knee jerks acute bed sores bladder trouble and she died in November from gradual heart failure after constant vomiting From first to last her illness occupied just 18 months Post mortem examination showed on the posterior surface of the cord just above the lumbar swelling beneath the pia mater a slightly raised rather dark looking patch On each side of this was a black looking vein filled with clot, contrasting with the almost empty pink looking veins elsewhere Section showed soft greyish looking tissue replacing in part the white and grey substance of the cord Sections through the lumbar cord showed in some parts of the anterior and lateral columns grey semi gelatinous patches In the mid dorsal region the whole transverse area of the cord flowed out on section having an opaque grey colour In the *mid cervical region sections showed grey gelatinous patches occupying various portions of the axis*

In the present state of our ignorance regarding the etiology of insular sclerosis there is no advantage in disguising the fact that we are unable to point to any mode of treatment which appears to influence the progress of this disease It becomes then a question of considerable importance whether the remarkable tendency to the occurrence of remissions and relapses in its course is calculated to throw any light on the mode of its causation As it seems to me the most likely view (and possibly that which finds most favour) is that *in insular sclerosis the essential cause is the presence* in the blood vessels of an infective agent which sets up an inflammatory process in the interstitial tissue This may occur at any part of the cerebro spinal axis On the other hand it has been suggested that the pathological process is essentially dependent upon some congenital abnormality I am disposed to think that such an explanation must be set aside The grossness of the anatomical findings alone would seem to be inconsistent with such an hypothesis Besides this insular *sclerosis cannot be said to be a family disease which might be expected were the disease of congenital origin* It is in my experience exceedingly rare to meet with more than one example in a family Diseases of the nervous system of endogenous origin are usually characterised as well by the fineness of the changes observed *in the structures involved* as by their slow and comparatively steady progress uninterrupted by any important tendency to marked remissions and relapses On the other hand if we turn to diseases of exogenous origin we shall find that in one undoubtedly and pre eminently of infective origin—syphilis—we are apt to meet with this peculiar feature very distinctly *exhibited* Thanks to the fact that specific treatment in syphilis has a powerful and very definite influence upon most cases of the disease it is quite likely that the tendency to recovery followed sooner or later by relapse in *that disease is a good deal obscured* But even as it is that tendency is constantly showing [illegible] when the beneficial effects of the

gummata endarteritis and the like For the most part the changes in insular sclerosis may be said to be of gross character It is true that some observers have pointed to the fact that occasionally the anatomical appearances in insular sclerosis cast some doubt upon the more usually received opinion that the disease is of inflammatory origin Redlich *for example amongst* others has found in insular sclerosis nerve fibres profoundly affected along with relatively little-changed neuroglia, and says that vascular changes happen only in a certain number of cases. But, as I have pointed out on another occasion, this is by no means conclusive. Parenchymatous degeneration of the posterior columns in a case of tabes may be accompanied by gross intracranial endarteritis. Presumably, therefore, a toxin may give rise coincidently to each form, and in some cases of insular sclerosis—or in some localities in a particular case—its influence may fall upon the nerve fibres rather than on the vessels and interstitial tissue.

The remarkable variations in the degree of acuteness in insular sclerosis, again, appear to be much more consistent with an infective than an endogenous origin. I have had cases under observation in this hospital in one of which 15 and in another 19 months only had elapsed from the commencement of symptoms and death. One that I met with in private (which was not, however, verified by necropsy) lived only 12 weeks. Ribbert examined anatomically one that survived only for three months. More often, as is well known, a far longer period characterises these cases, which may drag on for ten or 20 years or more.

We are well accustomed to the differing degree of acuteness in all forms of infective disorder, due probably either to intensity of the infecting agent or diminished power of resistance. In Friedreich's ataxia, on the other hand, to instance what is probably an example of congenital defect, the course of the disease is practically uninterrupted and chronic in character.

I fail also to see adequate grounds for the suggestion which has been more recently offered that insular sclerosis is the result of a toxic influence upon an existing defect of development. The presupposition of such a congenital defect appears to me as unnecessary as it would be in the case of infantile paralysis or of the neuritis which so often is a sequel of diphtheria. The frequency with which insular sclerosis attacks persons of exceptionally fine physique, the extreme rarity of its occurrence in more than one member of a family, as well as the marked remissions—often amounting to temporary recovery—which may take place in its course, appear to be inconsistent with such an explanation and to be much more in accord with the view that the disease is purely of toxic origin.

A Clinical Lecture

ON

TWO CASES OF HEMIPLEGIA.

Delivered at the Liverpool Royal Infirmary on May 31st, 1904,

BY T. R. BRADSHAW, B.A., M.D. DUB., F.R.C.P. LOND.,

PHYSICIAN TO THE INFIRMARY; LECTURER ON CLINICAL MEDICINE IN THE UNIVERSITY OF LIVERPOOL.

GENTLEMEN,—I wish to bring to your notice two cases of hemiplegia of sudden onset in young patients, cases which present a superficial resemblance to each other but which differ essentially in their pathology, prognosis, and treatment. Sudden hemiplegia is always the result of some vascular lesion in the brain, generally hæmorrhage, less frequently embolism or thrombosis. Embolism requires the existence of a clot formed in some other part of the body, generally in the heart, and carried by the blood into a vessel in the brain; thrombosis generally arises from a diseased state of the arterial walls accompanied by narrowing of the lumen. Hæmorrhage likewise indicates disease of the arterial walls but of a kind which leads to rupture under the pressure of the contained blood. There are practically only two conditions which give rise to arterial disease—viz., senile degeneration and syphilis—and consequently we may safely assume that hemiplegia in a patient under the age of 40 years is due primarily to valvular heart disease or to lues venerea.

The first case is that of a man, aged 25 years, a hairdresser, who has had right hemiplegia for a year. Two years ago he contracted syphilis and was treated for it, as he says, for seven months; but we do not know the kind of treatment that was prescribed nor with what thoroughness it was carried out. No secondary symptoms were noticed and he remained in fair health for a year, after which he began to suffer from intense occipital headache which lasted three weeks. Near the end of this time the paralysis began. While he was shaving a customer he felt his right leg suddenly give way under him; he fell to the ground and found that he was unable to move his right arm and leg. After a few minutes power returned and he got up and walked home, a distance of about 200 yards. An hour later, as he was walking upstairs, he had another similar but more severe attack. He fell down, the right arm and leg and the right side of the face were convulsed, and there was involuntary micturition. The convulsions lasted nearly 24 hours. Speech was seriously interfered with, but consciousness, he believes, was not lost in either attack. He remained quite helpless and was confined to bed, but after three months enough power had returned in his leg to enable him to walk about with the help of a stick, while the arm remained useless. At the present time he presents the characteristic picture of chronic hemiplegia. There are spasm of the right side of the mouth and difficulty of articulation, the right hand is contracted and almost motionless, while the elbow, and still more the shoulder, can be moved fairly well. The right leg is stiff, the knee being generally kept straight and the foot over-extended, and he walks with the characteristic hemiplegic gait, the foot being moved forward in a segment of a circle with the hip tilted to the opposite side to avoid the toe catching in the ground. The knee-jerk is extremely lively and an ankle clonus is readily obtained. The other systems are normal and the general health is satisfactory. A small scar indicates the seat of inoculation.

In view of the early age of the patient and the absence of any possible source of embolism we should be justified in considering this as a case of thrombosis from syphilitic disease apart altogether from the history of infection. Two points in the history of the onset of the attack strengthen this supposition—viz., the occurrence of severe antecedent headache and the retention of consciousness during the attack. Severe headache in a person not previously liable to it should always suggest the possibility of syphilis. In this case it was probably due to localised basal meningitis which is a frequent manifestation of the disease. The significance of the retention of consciousness is that it points to the lesion being a thrombosis rather than a hæmorrhage or embolism. Cerebral hæmorrhages, except the smallest, are almost always attended by coma in consequence probably of the increase of intracranial pressure brought about by the effused blood, aided, it may be, by the shock or concussion arising from the coarse damage to the brain. In embolism, unless the vessel occluded is very small, consciousness is generally lost for a while. Here there is no question of increased intracranial pressure but there may well be a severe degree of shock. The arrest of the circulation in the district supplied by the obstructed artery takes place with absolute suddenness and the instantaneous arrest of function in a considerable mass of brain tissue may readily upset the balance of the whole organ.

In thrombosis, on the other hand, there can obviously be no increase of intracranial pressure and a large vessel is seldom obstructed all at once. Some slowing of the circulation through the narrowed arteries must take place before it is arrested altogether and where a large vessel has been occluded we often have evidence that the obstruction has commenced in some of the branches and spread from them to the main trunk. Hence there is an absence of shock and the surrounding parts have time to adapt themselves to the changed conditions. The first paralytic seizure, from which recovery took place, suggests a temporary arrest of the circulation, restoration being due either to the obstruction not being complete or to the establishment of a collateral circulation. Either explanation is consistent with a state of the arteries predisposing to thrombosis.

We conclude, therefore, that this patient is suffering from the consequences of thrombosis of some of the vessels in the left side of his brain, the thrombosis being the result of syphilitic disease of the arteries. The onset of paralysis at so early a period, one year, after infection, is worth notice, though it is not so uncommon as to throw any doubt on the correctness of the diagnosis. The prognosis is good so far as life is concerned. We may with some confidence assure the patient that if proper treatment is carried out there will be no extension of the paralysis. We cannot restore the portion of his brain which has been deprived of its blood-supply but by perseverance he may train the remaining portions to take on some of its functions and he may educate his left hand The treatment will consist chiefly in the administration of mercury and iodide of potassium and in the performance of appropriate exercises for the muscles

The next case is that of a woman, aged 22 years who has had left hemiplegia which came on suddenly a fortnight before admission She had rheumatic fever in childhood and scarlet fever at the age of 14 years but had no other illness of importance till the beginning of April this year when she had some pain in the left foot followed by headache A few days later on awaking in the morning she found she was unable to move her left arm and leg In view of the age and sex of the patient and the sudden onset of the hemiplegia I was prepared to find a source of embolism in the existence of well marked mitral stenosis In this however, I was mistaken There were no presystolic murmur no substernal pulsation and no notable accentuation of the pulmonary second sound Further, there was a soft systolic murmur heard at the apex The impulse was felt chiefly in the fourth left interspace and it was doubtful whether there was any cardiac hypertrophy We know from experience that mitral stenosis is by far the most *frequent cardiac lesion which gives rise to embolism* The dilatation of the left auricle in this condition favours coagulation of blood in the appendix and a portion of the clot may break off and be carried away by the current of blood The absence of mitral stenosis therefore seemed to throw some doubt on the correctness of the diagnosis of embolism and the doubt was strengthened by the history of premonitory headache After the first three days however, we found that the patient s temperature, normal on admission assumed a hectic type rising in the evening to about 102° F and falling in the morning to about 97° and I began to suspect that we had to do with a case of infective or ulcerative endocarditis This suspicion was strengthened by our finding some enlargement of the spleen and it was placed beyond doubt by the discovery of streptococci in the blood from which cultures were obtained on two occasions

Here we have a case of hemiplegia depending on embolic obstruction of a vessel in the brain the embolus having arisen from a septic inflammation of the endocardium and the hemiplegia is really symptomatic of infective endocarditis The premonitory headache, unlike that noticed in the previous case, was clearly not due to a local condition but to the toxic state of the blood and was analogous to the headache of specific fevers

The prognosis in this case is obviously much graver than in the former In neither case can we expect complete restoration of movement to the paralysed parts but in the second we have to deal with a constitutional condition which is but little influenced by therapeutic measures and behind this we have a certain amount of permanent damage to the heart

Infective endocarditis is one of the most fatal diseases with which we are acquainted but recovery though rare is not unknown and the prognosis becomes better the longer the case lasts The treatment must be chiefly directed towards maintaining the patient s strength and moderating the fever Quinine in full doses is frequently prescribed and in a case under my care some years ago its administration was followed by recovery Antistreptococcic serum has been frequently employed but the results have been disappointing In the present case it has been administered hypodermically in 30 cubic centimetre doses on 11 nearly consecutive days without producing any obvious effect on the temperature or the other symptoms Subsequent examination of the blood however did not yield any evidence of the presence of micro organisms but how far the serum therapy employed is to be credited with the disappearance of the streptococci is open to doubt

---

METROPOLITAN HOSPITAL SUNDAY FUND —The total amount received at the Mansion House on behalf of the Metropolitan Hospital Sunday Fund up to Tuesday evening was £46 000 to which may be added about £11,000 as Mr George Herring s generous contribution, leaving about £7000 still to be made up if the fund this year is not to fall below that of last year

ON VINCENT'S ANGINA

BY H W BRUCE, M D B S LOND , F R C S ENG ,
OUTHWARK UNION INFIRMARY
PARK FEVER HOSPITAL,
JMS BOARD

VINCENT S angina is a form of pseudo diphtheria which is associated with, and is probably due to, certain characteristic micro-organisms The membranous or pseudo membranous affections of the pharynx which do not depend on the presence of the diphtheria bacillus are worthy of very careful attention Early diagnosis is of great importance and depends mainly on bacteriological examination If the clinical features of these affections be alone relied on in the early stages to reveal the nature of the disease they will very frequently indeed be mistaken for diphtheria and the dread which that disease still inspires and all the inconveniences of isolation will be inflicted unnecessarily upon the patient Treatment will be wrongly directed and prognosis will be faulty

The form of pseudo diphtheria illustrated by the ten cases on which this paper is based was first described by Vincent in 1898 His observations have been verified by many French and German writers since that date but so far as I can discover the disease has received very little attention from English observers It is I believe not uncommon but its frequency is, without doubt, masked, as Vincent surmised by the fact that it is still frequently confounded with diphtheria The pathological processes in the two diseases are, however quite different In Vincent s angina there is a necrosis of the mucous membrane which, spreading deeply, may involve *and destroy the whole thickness of the tonsil or the whole* of the uvula but which never gives rise to the formation on the surface of the mucosa of a thick false membrane such as occurs in diphtheria When a considerable amount of destruction of tissue has taken place the distinction is made readily enough But when as in the milder cases, the necrosis is very superficial or as in the more severe type at the outset the presence of the necrosed epithelium on the surface hides the depth of the lesion, the resemblance to diphtheria is very [illegible] can then only be made by [illegible] ich determines the absence [illegible] presence in large numbers of a typical bacillus with which is often associated a spirillum These micro organisms are fully described below

Clinical characters —The onset of Vincent s angina is often in children quite insidious In some cases there has been such an absence of symptoms that the affection has only been discovered during a routine examination of the throat In others attention is drawn by the glandular enlargement in the neck In a minority only is there at the outset complaint of sore throat or pain in swallowing It is however not always easy in the case of children to ascertain the presence or absence of a slight amount of dysphagia In adults headache general malaise or sore throat or a combination of these symptoms, may usher in the disease

Examination of the throat in the early stage shows what appears to be a patch of exudation situated on some part of one tonsil or on the upper part of a tonsil the upper part of the uvula on the same side and the edge of the soft palate between The latter situation is unusual in diphtheria and should arouse suspicion as to the nature of the complaint The pseudo membrane is yellowish or greenish yellow in colour It is detached only with difficulty leaving a bleeding eroded surface and it has a very distinct fœtor If this is not sufficient *to taint the breath it can be readily detected* by rubbing a swab on the patch The appearance of the throat in this early stage may exactly resemble that produced by the formation of the membrane of diphtheria But the after course of all but the mildest cases clearly shows that no such formation of membrane has occurred and that the patch is the result of necrosis of the superficial layer of the mucosa and not the result of the formation of membrane upon the surface

Mild or diphtheroid type —In the mildest cases, which Vincent has called "diphtheroid," the process does not extend over much of the surface nor penetrate to any depth It is invariably unilateral in such cases, which is again something of a distinction from diphtheria There is practically no swelling of the fauces and very little injection. Enlargement of the lymphatic glands in the neck is nearly always present on the side of the lesion but is never very great, is never accompanied by periglandular exudation, and never results in suppuration. The submaxillary group is most commonly affected.

The temperature is generally a little raised but it rarely exceeds 101° F. Constitutional symptoms, loss of appetite, and general malaise are but slightly marked. Adults may complain of dysphagia; its presence is not usually ascertained in children. In the course of from 24 to 48 hours the temperature falls to normal and the general symptoms disappear, but this does not coincide with any particular change in the condition in the throat. The necrosed patch only slowly separates, leaving generally a shallow but definite excavation which quickly heals over. From eight to ten days is the usual time which elapses before the tonsil has cleared up. In adults it may be shorter. There are no complications nor after-effects. The disease when it follows this type is in fact a mild one, of little moment. Its only importance lies in its resemblance to diphtheria, which, as far as symptoms and naked-eye appearances are concerned, continues throughout its course until the separation of the slough.

Ulcero-membranous type.—In these more pronounced cases the appearance of the fauces is at the commencement identical with that in the preceding group but the process soon extends over the surface and involves the mucous membrane more deeply. The whole of one tonsil may be affected with the adjoining pillars of the fauces and the adjacent edge of the soft palate and side of the uvula may be attacked. The lower edge of the pseudo-membrane may be beyond the field of vision and frequently ordinary examination reveals only a small area of necrosis, while by thoroughly depressing the tongue and inducing retching a very large patch is brought into view. The disease but rarely involves the other side of the pharynx.

It is not until three or four days after the onset that it becomes clear that a destruction of tissue is taking place such as does not occur in diphtheria and the case then loses all resemblance to that disease. These cases Vincent describes as first diphtheroid and later ulcero-membranous. The process having ceased to extend, a slow separation of the slough takes place. This generally takes from ten to 14 days, but may be much longer. The whole surface of a tonsil or its whole substance may separate, leaving a deep excavation. Necrosis of the upper part of the uvula and of the tonsil and of the edge of the soft palate between may lead to an increase of the aperture of the fauces in this region. Half of the uvula may be destroyed. This occurred in Case 1. The part of the uvula which escaped, which was little more than a shred, was drawn up to the opposite side and became unrecognisable. In extreme cases the whole uvula may be attacked and come away as a grey foul slough. This took place in Case 10. During the process of separation of the necrosed mucous membrane granulations appear on the surface which bleed readily when touched. When once the surface has cleared up healing quickly occurs. If there has been much loss of tissue some contraction may result as in Case 1. With the condition in the throat there is always a certain amount of pyrexia, which is, however, seldom very marked or prolonged. Difficulty in swallowing may persist for a few days, and while the temperature is raised constitutional symptoms, headache, loss of appetite, and general malaise are present. There is, as in the preceding group, very little swelling of the fauces and generally not much reddening. In severe cases, however, a zone of intense injection may surround the affected area. Some enlargement of the glands of the neck is invariable, but is small in amount and does not go on to suppuration. Albuminuria is very rarely present. Case 9 recorded below is the only instance I have found of its occurrence.

In the majority of cases complete recovery ensues, the only after-effect being an occasional drawing down of the palate to one side as a result of the contraction which occurs in the healing process. But although the tendency of the disease is generally towards recovery a special virulence of the causative agent or a special susceptibility of the patient may result in the lesion spreading widely through the pharynx and becoming then a serious menace to life. Cases 9 and 10 illustrate extreme results of the necrotic process. In both death ensued: in the first seven days after the onset, apparently from toxic absorption from the site of disease; in the second the disease spread to the larynx and gave rise to necrosis of the thyroid cartilage. Suppurative broncho- [illegible] to which the patient succumbed on the [illegible] his illness.

Prognosis.—It is impossible at the present time to ascertain even approximately the death-rate in Vincent's angina. It can only be said that it is very much lower than in diphtheria. Cases as severe as those mentioned above are in all probability quite [illegible] are said to occur and one attack doe [illegible]

Bacteriology.—Cultivations taken from the throat in this disease do not yield characteristic results. The growth which occurs is composed of different micro-organisms, the pyogenic cocci being the most frequent. The bacillus coli communis is occasionally present (Vincent, Raoul and Thiry, Lemoine) and the pneumococcus has been observed (Neissler) mixed with other cocci. If, however, a little of the exudation be rubbed on a slide and stained with any aniline dye a characteristic bacillus is seen in great numbers and with it is frequently associated a spirillum. The relative numbers of the two vary. In the mild diphtheroid cases the bacillus always greatly predominates. Vincent, in fact, states that it may be exclusively present. In the ulcero-membranous type, on the other hand, the spirillum is much more frequent and may even be present in greater numbers than the bacillus.

The bacillus which Vincent has called the "fusiform bacillus" is very long (from 10 to 12 μ generally). Its centre is a little thickened and its ends somewhat pointed, giving rise to the typical fusiform shape from which it has derived its name. Two bacilli arranged end to end are sometimes seen, but apart from that it is usually distributed uniformly through the field. It may be present in such numbers as to form almost solid masses. Shorter forms are seen (from 6 to 8 μ), occasionally curved and comma-shaped. Very long, badly-staining bacilli are also sometimes present, and now and then a bacillus is seen which is greatly swollen in its centre, the expanded part not taking up the stain while its edges are defined by a thin dark line. The bacillus is readily stained by aniline dyes but frequently not uniformly. One or more clear spaces are present in its length. These may not be visible if it is stained too deeply. It does not yield the Neisser staining reaction and it is decolourised by the Gram method. Its motility is doubtful. So far all attempts to cultivate it have failed.

The spirillum is only faintly stained by the ordinary reagents. It is decolourised by the Gram method, is motile, and, like the bacillus, has never been cultivated. At the commencement of the disease either the bacillus or the bacillus and spirillum are found almost pure in the pseudo-membrane. Later they become mixed with numerous other micro-organisms which inhabit the mouth. Even then the bacillus has been found isolated in the deeper parts of the lesion (Vincent). The spirillum, on the other hand, is always most numerous on the surface. Inoculation of animals with portions of the false membrane has not produced any definite result.

Both the above micro-organisms, or, at least, organisms exactly resembling them, have been found in small numbers in the mucous membrane of the mouth and pharynx in the normal state. They have also been found in dental tartar. In membranous and ulcerative diseases of the pharynx, the bacillus, like other micro-organisms which inhabit the mouth, may be present in the lesion, but only in very small numbers. A spirillum indistinguishable from the above has been found in abscesses adjoining the buccal cavity.

The question as to whether these micro-organisms are the actual causative agents in the disease cannot yet be considered settled. The failure to cultivate them makes it impossible definitely to decide the point. Their presence in such large numbers and so constantly makes it, however, very probable that the pathological process which occurs is due to their presence. Vincent, arguing from the fact that it is alone present in some cases, considers the bacillus the more important factor; recognising at the same time that the spirillum, since it occasionally predominates in numbers, must be of importance in the etiology. It is possible that the growth of the bacillus is aided in some way by the presence of the spirillum.

The relation of Vincent's angina to hospital gangrene and to ulcerative stomatitis.—Opportunities of observing hospital gangrene or phagedæna are nowadays very rare but Vincent, in 1895 and 1896, was able to make a bacteriological examination in a number of cases which he saw in Algiers.

[illegible] ction, and in their resistance [illegible] them were identical with the [illegible]

The resemblance between the lesion in the two diseases is very close indeed. It differs, in fact, only in locality and it is of great interest to find that they are both associated with the same micro-organisms. Bernheim in 1898 first drew attention to the presence in ulcerative stomatitis of bacilli and spirilla apparently identical with those which had already been observed in certain anginas. His statements have been verified by several writers since. Case 4 and 7, described below, both presented a localised ulcerative stomatitis in addition to the throat condition, and in both cases fusiform bacilli and spirilla were present in large numbers in both buccal and faucial lesions. In a case of more general ulcerative stomatitis occurring in a woman dying from carcinoma of the rectum I found the same micro-organisms in great profusion.

In conclusion, I have to express my indebtedness to Dr. R. A. Birdwood, medical superintendent of the Park Fever Hospital, and to Dr. J. S. Richards, medical superintendent of the Southwark Union Infirmary, for permission to publish the cases related below.

Case 1.—The patient, a girl, aged eight years, was taken ill on Sept. 12th, 1903. On the 13th she complained of headache and sore-throat, on the 14th glandular enlargement in the neck was noticed, and on the 18th she came under observation. Her temperature was 101° F. The right tonsil, the right side of the uvula, and the edge of the soft palate were then covered with a fœtid greyish-yellow pseudo-membrane. The lower edge of the affected area could not be seen. On the 21st the slough was separating and by the 28th it had separated, leaving a deep excavation where the tonsil had been, while the uvula which remained was merely a shred. The edge of the soft palate was also hollowed out. Small granulations covered the healing surface. The shred of uvula was almost at once drawn up to the opposite side and in a short time could not be recognised. No complications ensued. A month later there was some drawing down of the soft palate towards the affected side.

Case 2.—The patient, a girl, aged three years, did not seem well on Oct. 17th. She appeared to have some difficulty in swallowing on the 18th when she came under observation. Her temperature was 100·6° F. The upper part of the left tonsil, the upper part of the left side of the uvula, and the edge of palate between was covered with what looked like greyish exudation. There was distinct fœtor. On the 20th there was a little glandular enlargement in the neck and the necrosed patch showed signs of separating. The throat was not quite clear till the 30th The temperature fell to normal on the third day. The angle between the uvula and the tonsil was considerably enlarged by the loss of tissue which had occurred.

Case 3.—The patient, a girl, aged three years, was taken ill with vomiting on Oct. 23rd and was first seen on the 24th. The temperature was 100·4° F. There was a greenish-yellow patch on the tonsil with fœtor. On the 26th the temperature was normal. The throat had cleared up by the 30th, a shallow but distinct excavation remaining which quickly healed over.

Case 4.—The patient, a boy, aged five years, presented no symptoms of illness. On Dec 22nd, in course of routine examination, a yellowish-white patch was seen on the right tonsil, and the temperature was found to be 100° F. On the 23rd a submaxillary lymphatic gland was enlarged. The temperature had fallen to normal. A limited area of ulcerative stomatitis was present surrounding two lower molar teeth which were quite loose. Fusiform bacilli and spirilla were found in large numbers in the ulcerated area. The throat very slowly cleared up. It was not normal till Jan. 8th.

Case 5.—The patient was a boy, aged three years. On [illegible]

[illegible] the same side. The temperature w[illegible] child did not appear in any way ill. There was distinct [illegible] at cleared up in ten days, no other symptoms developing. In this case the spirilla were more numerous than the bacilli.

Case 6.—The patient was a boy, aged three years. Attention was drawn to this case by glandular enlargement in the neck. A patch was found on the left tonsil. There were no rise of temperature and no other symptoms. The throat was clear a [illegible]

Case 7.—The p [illegible]
ing from congeni [illegible]
attention was draw [illegible]
lymphatic glands. A patch of greenish pseudo-membrane covered the upper part of the left tonsil and the angle between it and the uvula. There was also, as in Case 4, a localised ulcerative stomatitis about the lower temporary molar teeth on one side. Bacilli and spirilla were present in both lesions. Fœtor was marked. The throat cleared up in 12 days.

Case 8.—The patient, a female, aged 25 years, was attacked with headache and general malaise on March 1st. On the 2nd there were sore throat and a little glandular enlargement on the left side of the neck. A greyish patch was present on the left tonsil. On the third day the temperature was normal and the patient felt well but the condition of the throat was unchanged. Two days later it had cleared up.

Case 9.—The patient, a girl, aged eight years, came under observation on April 8th, 1903. She had been ailing since the 5th; she had complained of headache but not of sore-throat. Her temperature was 104° F. A thin greyish pseudo-membrane covered the left tonsil, the left side of the
uvula, [illegible] r was
very m[illegible] n the
neck. [illegible] eudo-
membrane was thicker The general condition of the child was distinctly worse. She was very restless. On the 10th the slough was greenish-yellow, exceedingly foul, and had invaded the right side of the pharynx. A cloud of albumin was present in the urine. On the 11th both tonsils and the whole of the uvula were covered by slough. Swelling of the fauces was very slight, as it had been all along. A narrow zone of intense injection surrounded the necrosed area. The temperature was irregular but had never fallen below 101·6°. On the 12th foul diarrhœa set in. The child was exceedingly pale and slightly jaundiced. Her condition became steadily worse and she died at midnight. At the post-mortem examination the whole of the fauces, the base of the tongue, and the epiglottis were covered by a greenish-yellow foul slough. The organs were healthy.

Case 10.—The patient, a boy, aged nine years, had suffered from headache and sore-throat for a week before he came under observation. There was then a yellowish pseudo-membrane covering the right tonsil, the right side of the uvula, and the edge of the soft palate on the right side. The temperature was 100° F. There was a little glandular enlargement in the neck. During the next few days the pseudo-membrane became a definite slough which, increasing in size, involved the whole thickness of the right tonsil and of the uvula. The left tonsil was also attacked over a limited area. On the fourteenth day of illness the sloughs were definitely separating and by the twentieth day the right tonsil had completely disappeared, leaving a deep excavation. On the same day the uvula was picked off with forceps as one slough. Sprouting granulations appeared over the raw area left by the separated sloughs. During this period the temperature had been very irregular but always raised and the breath had been very foul. By the twenty-eighth day the fauces had healed. On the next day but one some tenderness and swelling appeared over the thyroid cartilage. This was followed by aphonia, slight stridor, and expectoration of pus. The temperature was higher. From this time onwards the patient went steadily downhill. A little stridor persisted but there was never sufficient respiratory obstruction to necessitate tracheotomy. Signs of consolidation appeared over the left lower and the right upper lobes. There was profuse purulent expectoration, great tenderness over the larynx but very little swelling, and persiste [illegible]
[illegible] hirty-sevent [illegible]
[illegible] ion to the [illegible]
[illegible] ces the righ [illegible]
[illegible] l. The anterior part of the thyroid [illegible] necrosed and lay in small pieces in a cavity which opened into the larynx in front. The walls of the

cavity and the edges of the opening were green and sloughy. There was much swelling of the upper aperture of the larynx. The right upper and the left lower lobes of the lungs were affected throughout with broncho-pneumonia which had in many places broken down, giving rise to multiple abscesses. The other organs were healthy.

DIET IN CHRONIC HEART DISEASE.

BY PROFESSOR THEODOR SCHOTT, M.D.

AS a kind of supplement to a discussion which took place at a meeting of the British Balneological and Climatological Society in the spring of last year and, moreover, in accordance with the express wish of numerous practitioners, I will now endeavour briefly to pass in review some general rules with respect to the diet which I have found satisfactory in the treatment of chronic heart disease during the year. Only such points will be discussed at length as have a direct relation to heart diseases.

The principal rules, which are, in fact, to be regarded as fundamental, may be conveniently summed up in the two following clauses: (1) patients must avoid everything which excites the action of the heart; and (2) everything must be avoided which embarrasses the action of the heart.

The substances which most readily cause excited action of the heart are in the first place strong coffee or strong tea and in the next place strong alcoholic liquors. It is to be observed that in persons who from youth upwards have made free use of coffee or tea, either in great quantities or in strong infusion, if they come to suffer from heart disease a relatively small quantity of such habitual stimulants will be found to aggravate the cardiac symptoms. This is the reason why in Germany the medical men are just as strongly opposed to coffee drinking by sufferers from heart disease as in England they are opposed to tea-drinking in like circumstances. With regard to alcohol, its use as a daily beverage in an undiluted form, whether whisky or brandy, must be avoided as much as possible, and it must in any case be given only to patients for whom it is either indispensable as a stimulant or who have taken it for so many years that the sudden withdrawal of it might be dangerous in view of the possibility of collapse. In such cases the best plan is to give Rhine wine, Moselle, or Bordeaux which has been matured (*gelagert*) for eight or ten years, because in newer wines there is not only a larger proportion of fusel oil but experience also shows that there still exist too many fermentable substances which may very easily act injuriously. A tablespoonful of old Cognac brandy or whisky for some patients and an ounce of old sherry or port for others are almost indispensable as stimulants in cardiac weakness, but, as has been already said, if taken regularly they are capable of doing harm by producing cardiac irritability. It must here be remarked that a light or diluted wine agrees best with patients in Southern or Central Europe, whereas in Northern Europe, and especially in damp northern climates, a typical example of which is to be found in Great Britain, preference should, on the contrary, be given to Cognac brandy or whisky mixed with plain water and diluted until the proportion of the alcohol component is reduced nearly to that of moderately strong or even light wines. It is very necessary to forbid the addition of aromatic substances (such as ginger) to the alcohol, for simultaneous irritability of the stomach and heart often lead to loss of appetite and insomnia.

Moderate quantities of ordinary water or milk are by far the best beverages; next in order come tea or coffee, both of them with copious addition of milk. Patients for whom some fatty material is desirable may take cream either by itself or mixed with milk. Sterilised cream agrees better with many patients and it has the further advantage that it is not apt to produce flatulence. Cocoa deprived of its fat can be strongly recommended, whereas chocolate is seldom found to agree well, either on account of the quantity of sugar which it contains or from the slow digestibility of cocoa fat, and the vanilla present in it often has the effect of exciting the heart. The amount of fluid which may be taken at one and the same time will be referred to presently.

With respect to the second rule above given, it is of the first importance that the patient should avoid taking enough to cause any considerable distension of the stomach and that he should eat nothing which is difficult of digestion or tends to produce flatulence. It hardly requires to be explained in detail how indigestible substances remain too long in the stomach and prove injurious in consequence of the intimate connexion between the nerves of the heart and stomach. Too hearty eating or the ingestion of substances which produce flatulence may be harmful in three ways. 1. The diaphragm is pressed up against the lungs so that respiration is impeded and the shortness of breath and dyspnœa thence arising are well known to be peculiarly injurious to sufferers from heart disease. 2. The distended stomach also presses the diaphragm directly against the heart, forces the heart upwards and outwards, and displaces it in the direction of its base in such a way that its action can only be carried on with a greatly increased effort. 3. In like manner the intra-abdominal pressure is augmented and the abdominal vessels are compressed. The general result is that the heart is weakened and the cardiac muscle not unfrequently suffers in the struggle. For this reason effervescing beverages, whether carbonated water, champagne, or beer, for the most part disagree with patients who are the subjects of heart disease. In the case of beer, which is essentially the product of an artificially interrupted carbonic acid fermentation, the irritant properties of the extractives which it contains have also to be considered. Palpitation, shortness of breath, and conditions favourable to arterio-sclerosis are only too often met with as after-effects of effervescing alcoholic drinks.

As such patients must never eat until a feeling of repletion is induced the generally accepted system of having three meals a day is not advisable for them and it is much better to take small amounts of food at shorter intervals. If the patients are very weak or very ill it may be necessary for them to have food every two hours, but in general food every three hours is often enough, the last meal of the day being taken two and a half or three hours before bedtime, for if this is neglected the result will be a bad night or at least broken sleep, which is apt to be followed by general irritability and cardiac difficulties of many kinds. If in any way possible, each of the daily meals ought to have about the same nutritional value, because this, apart from its utility for digestion, conduces best to a uniformly beneficial effect on the heart. With regard to individual dishes it must in the first place be specially pointed out that it is not advisable to take considerable quantities of soup, because from the meat extractives which they contain soups in general, and either clear soups made from fresh meat or consommés in particular, are apt to produce a disturbing effect out of proportion to their nutritional capacity. Even soups of which any kind of solid addition (*Einlage*) forms a part have but little food value in proportion to their bulk, so that no more than a moderate quantity (only a few tablespoonfuls) can be recommended, for larger amounts interfere with the taking of really useful substances. New bread, whether brown or white, and freshly baked cakes are totally to be avoided, for they too often cause distension of the stomach and great flatulence. Toast, zwieback (a kind of rusk or "pulled bread") made without sugar, or the crust of rolls may, however, be taken. Among vegetables those are to be avoided which are either difficult of digestion or productive of flatulence, such as beans, peas, lentils, sauerkraut (preserved cabbage), red cabbage, leeks, onions, garlic, and celery. Potatoes in the form of purée or simply boiled in water are to be preferred to the less digestible baked potatoes. Turnips and carrots should be eaten only when fresh and young. In other respects, fresh and easily digestible vegetables cannot be too highly commended.

Animal food, in its various forms, especially fish and poultry, are allowable, but it hardly needs to be said that *certain indigestible articles included under the heading of* fish and poultry are to be forbidden; eels, fat goose breasts, and goose-liver pies are examples of this kind. The same rule applies to rich sauces or mayonnaise, for salmon, lobsters, and crabs taken with these accompaniments are much more trying to cardiac patients than they otherwise would be. Oysters, mussels, and game (*Wildbret*) seldom do harm if fresh and prepared in a plain style, but highly smoked and salted fish or meat are objectionable because the great thirst which they produce easily tends to too much water being drunk. Among fatty substances butter and cream are by far the best, being easy of digestion. Fat bacon or the fat on a ham is, on the contrary, to be avoided on account of its indigestibility. The same rule applies to the hearty eating of fat. Oil generally does not agree well. Hot seasonings are injurious, red and black pepper being worst of all. *They not only* produce gastric irritation and great thirst but they have a specially harmful influence on the kidneys, an influence which in cases of weak heart may lead to conditions full of danger. Sausages, goulasch (a kind of meat stew), and salads containing pepper are therefore to be avoided. On the other hand, vegetable salads without hot seasoning, and particularly when made with lemon-juice, are permissible. There are many other seasonings or spices, such as nutmeg, mace, cinnamon, and vanilla, which are capable of doing harm by their tendency to quicken the action of the heart. The same thing may be said of horse-radish, which not only is apt to produce flatulence but also irritates the mucous membrane.

Easily digestible fruit stewed with the addition of a little sugar can be recommended, particularly on account of its favourable influence on gastro-intestinal peristalsis which is *often so much impaired in heart disease that obstinate* constipation is the result. For the same reason raw fruits which have to be peeled, such as apples, pears, apricots, peaches, and oranges, are often desirable. Grape-stones may act as irritants and should be removed before the fruit is eaten. On the other hand, raspberries, gooseberries, currants, bilberries, cranberries, pineapples, walnuts, Brazil nuts, and hazel nuts are to be prohibited, even when deprived of their membranous investment, for they may be injurious to sufferers from heart disease either from their indigestibility or from irritant substances which they contain. Only those kinds of food which are quite easily digestible can be recommended.

Ice in any form whatever, whether as iced drinks, fruit ices, or ice pudding, may not only cause gastrodynia in cardiac sufferers but, as I have often enough observed, is capable of directly producing congestion of the liver. This must be kept in mind even when the medical attendant is compelled to prescribe ice for the relief of vomiting. At the same time nothing should be either eaten or drunk while it is very hot, as excitement of the heart's action is easily caused in that way.

It is impossible to urge too strongly that sufferers from heart disease always require a mixed diet. With them the use of a diet consisting exclusively of meat very easily leads to the excretion of urine containing an excessive amount of dissolved solids and supersaturated with uric acid. I have even seen cases in which over-indulgence in animal food appeared to have been the principal, if not the only, cause of irritation of the kidney with hypertrophy and dilatation of the heart. An entirely vegetable diet is no less injurious. In order to make up the requisite amount of nutritive material, such *food must be taken in considerable quantities*, whereby the stomach is over-filled, and apart from this the supposition that arterio-sclerosis may be prevented by a dietary consisting of carbohydrates has been proved to be erroneous. Indeed, the very reverse of this is the fact, for it has been found that calcification of the vessels is encouraged by such a diet. Thorough comminution and copious insalivation of what is eaten are as important in diseases of the heart as in diseases of the stomach.

There is great diversity of opinion on the subject of tobacco-smoking. Many think that smoking when not carried to excess is quite harmless in heart disease and others consider that even in the cases in which the patients have found their symptoms aggravated by the use of tobacco the normal conditions are sure to be restored by a few months' abstinence. My experience leads me to regard tobacco with great disfavour, for I have seen quite a number of instances in which an excessive use of it was the only cause that could be assigned for the production of chronic heart disease and arterio-sclerosis. In tobacco there are many substances besides nicotin that may act injuriously *and for this reason the* partial removal *of the alkaloid*, a process to which tobacco has often been subjected in recent years, is no guarantee that much smoking may have no ill consequences. I therefore always recommend patients suffering from heart disease either to give up smoking altogether or else to indulge in it most sparingly, and in the latter case to use very dry tobacco and a long mouthpiece or pipe. A patient should always be informed that smoking is bad for his heart disease. Some years ago I had an opportunity of observing how dangerous opium smoking is for the heart, the patient being a woman, 22 years of age. At first a great smoker of cigarettes and afterwards of opium, she gave up the practice for a considerable time when placed under strict supervision but the first attempt at renewal of opium smoking brought on a severe attack of cardiac failure for the relief of which it was necessary to use camphor and *hot applications over the heart.*

As a result of observations made by Oertel, it has been very much debated whether sufferers from heart disease ought to drink at meal times or not. I have, however, already stated that the only condition which requires attention here is that the stomach shall not be overfilled and the principal advantage of not drinking at meal times is that the patients when they do not drink eat less that when they drink. In the treatment of fatty heart and general adiposity, as well as in plethora, it is better not to drink but when it is desirable that the patients should have plenty of food there is absolutely no reason for the prohibition of drinking at meal times, provided that the measures of precaution already described are complied with.

The majority of sufferers from heart diseases feel themselves better if they take gentle exercise in the open air for *a short time after meals. Sitting still is apt not only to* bring on palpitation and shortness of breath, but also to encourage the deposition of fat; it is therefore appropriate only when the latter condition is desirable or when the patients are too weak to take exercise after meals. In other cases exercise after meals is to be recommended. In heart disease it is evidently quite essential that the individual characteristics of the patients should be studied and that the treatment should be modified in correspondence with the symptoms.

The rules here given are for the most part applicable to uncomplicated cases of chronic heart disease, whether valvular defects due to a variety of causes, diseases of the myocardium, or cardiac neuroses. Heart disease associated with other morbid considerations, such as diseases of the stomach, intestines, liver, or kidneys, or with disorders of metabolism such as diabetes or gout, evidently requires special treatment. The same regimen is not suitable for a bedridden patient and for a robust individual who can walk for hours in the open-air, or for anæmic persons and for cases of plethora or corpulence. Strict regulation of the diet is requisite not only in the pre-compensation stage but also after compensation is fully established, for it is commonly recognised how easily errors in diet may either contribute to a renewal of cardiac troubles or may directly produce them. I have often seen this result follow the drinking of a glass of beer or champagne or the taking of a *hearty meal. The practitioner should remember* that the more carefully he manages his cardiac cases during the intervals between their attacks the better will he succeed in averting relapses and in contributing to the relief of his patients' sufferings and even to the prolongation of their lives.

Bad Nauheim.

THE PHYSIOLOGICAL ACTION OF THE NAUHEIM SPRINGS AND THE INDICATIONS FOR THEIR USE, CHIEFLY IN DISORDERS OF THE CIRCULATION.

BY PAUL C. FRANZE, M.D.

ALTHOUGH Nauheim owes its present popularity in no small measure to an increased prevalence of heart affections, there can be little doubt that its widespread reputation is essentially *attributable to the intrinsic merits of its waters* and to the balneological methods which have been evolved by observation and experience. In Nauheim three springs, containing from 2·5 to 3·5 per cent. of the chlorides of sodium, lithium, and calcium, together with some iron, are available for bathing. Their most obvious attributes are their richness in free and loosely combined carbonic acid and their natural temperatures, which are respectively 29·5°, 32·5°, and 35° C. (i.e., approximately 85°, 90°, and 95° F.), temperatures which at once suggest themselves as suitable for bathing. From two of these springs three different types of bath are prepared and from one of them two types, the essential features of these baths being a greater or less proportion of free carbonic acid gas. For on the proportion of this gas, which can be graduated with precision, depends to a great extent the potency of the physiological action of the waters. The first and mildest type, the so-called thermal baths, contain least carbonic acid. They are obtained by admitting the water to large open reservoirs where, in contact with atmospheric air, the free carbonic anhydride escapes with a consequent precipitation of the calcium and iron salts which it held in solution. These salts colour the water yellowish-brown. With this bath we usually commence the treatment of cardiac cases. To the second type, containing a little more carbonic acid, belong the thermal-sprudel baths, obtained by conducting the water to subterranean air-tight tanks from which it is conveyed to bathing-tubs. This water is clear or slightly yellow owing to its having lost only a little of its carbonic acid gas. These baths are of an intermediate grade between the former and the effervescing baths. The third, the effervescing type, are known as the sprudel baths. They contain the full amount of carbonic acid with which the springs issue from the earth. The water is conveyed by pipes directly to each tub without the intervention of tanks or atmospheric contact. These baths are strongly effervescing, bright and sparkling, and clear as crystal. The most potent effect is attained by immersing the patient in a continuous current of this carbonic-acid-laden water. Clear brine baths, from which the carbon dioxide and the salts which it holds in solution have been removed by percolation through brush-wood, are also used at Nauheim. They contain some 3 per cent. of the chlorides and are prescribed with some measure of success as an adjunct in the treatment of rachitic, scrofulous and anæmic children. I do not propose to refer further to them in this paper.

On entering a Nauheim bath of natural temperature the following symptoms are observed. There is at the outset a slight sense of shuddering, soon, however, succeeded by a general sensation of warmth. In their earlier immersions cardiac patients occasionally experience a feeling of thoracic oppression which is, however, but transient and which disappears entirely in succeeding baths. In a sprudel, or effervescing, bath the body is soon completely covered with countless bubbles of carbonic acid gas. After ten minutes' immersion the patient's temperature, taken in the rectum, falls about 0·2° C. In five minutes more a further fall of from 0·1° to 0·2° is not infrequently observed. Hyperæmia of the skin supervenes to an extent dependent on the amount of carbonic acid and salts employed. On the patient quitting the bath and being rubbed down the glow becomes more marked; the pulse also becomes stronger, more regular, and usually, though by no means invariably, slower. The blood pressure is sometimes raised and sometimes reduced—a matter to which I shall presently revert—and respiration is easier. Ordinary bathers feel themselves refreshed but the more delicate patients occasionally experience a sense of lassitude, especially after their earlier baths. If a delicate patient at the outset takes a bath containing a high proportion of the gas, excitement, fatigue, and disturbance of the heart's action may ensue. These various effects produced by the baths are attributable to the stimulation of the skin by means of the salts, the carbonic acid, and the temperature of the water. The elements in the skin which respond to these influences are the terminations of the cutaneous sensory nerves and the capillary vessels.

The temperature of a bath is an important factor in the production of its general effect. At a temperature of about 2° C. below blood-heat the influence of a bath, save as a detergent, is practically *nil*. We term this temperature—35° C.—the "point of indifference." Should the water be warmer the temperature of the body is increased and a number of changes take place in the circulatory system which are usually undesirable and to which I need not advert as these higher temperatures are not prescribed at Nauheim. We only employ those below and up to the "point of indifference," which the Nauheim waters naturally possess. In baths of the latter kind the body loses heat and as our system has the tendency, and in large measure the capacity, to maintain its normal temperature, the consequence is increased production of heat. It is known that increased exhalation of carbon dioxide corresponds to this. Coincidently there is increased excretion of urea, proving that the metabolism of nitrogenous matter is also accelerated. The most obvious physiological explanation of this improved metabolism is that the peripheral nerves convey their stimulus to the spinal cord and sympathetic centres by which it is controlled. Next we notice changes in the circulation. On entering the bath there are acceleration of the pulse and contraction of the peripheral vessels of the skin and subcutaneous tissue. Internal congestion ensues. Soon, however, the contraction ceases, the superficial vessels dilate, the pulse becomes slower and stronger, and "reaction" is manifest. This also is due to reflex action, the stimulus being conveyed to the pneumogastric nerve centres which, in their turn, control the heart.

It is very important to remember that although these changes occur in a Nauheim carbonic acid bath which is but a few degrees below the "temperature of indifference," they are not induced in an ordinary fresh water bath, except at such low temperatures as would throw an absolutely impermissible initial strain upon a debilitated heart. This is a most remarkable feature of Nauheim baths and it is essentially attributable to the salts dissolved in the water and to the carbonic acid gas, for these ingredients intensify the stimulation of the skin and modify the action of the cold. The aggregate result is that in a Nauheim bath reaction supervenes much sooner and with greater intensity than is possible with ordinary fresh water. Although it is improbable that any of the salts completely permeate the skin it would appear that they are imbibed by the epidermis sufficiently for direct stimulation of the peripheral nerve terminations and capillaries of the corium. Imbibed by the epidermis the salts maintain their action for some time after the conclusion of the bath. The entire nutrition of the skin is thus increased, it holds a greater amount of blood, and its excretory functions exhibit a revivification which is more than transitory.

Tissue metabolism is accelerated and researches as to the physiological action of chalybeate baths rich in carbonic acid show that this gas chiefly promotes the metabolism of non-nitrogenous matter. This, of course, is especially applicable to the effervescing sprudel baths. The acceleration of tissue metabolism promotes the absorption of exudations in the joints, pelvic and serous cavities, and it is known that Nauheim baths are among the most efficient means of removing the sequelæ of rheumatism and gout, of serous inflammations, such as pleurisy and pericarditis, and of inflammatory conditions of the uterine adnexa.

Since the large majority of patients come to Nauheim for the relief of some affection of the heart or circulatory system I would advert especially to this class of cases. The effect of the mineral baths on the heart is twofold—namely, (1) the mechanical removal (by the "reaction") of obstacles to the circulation at the surface, and (2) the reflex action on the heart and blood-vessels generated by peripheral stimulation of cutaneous nerves.

[Dr. Franze here discusses at some length the physiology of the circulation and the part played by the vessels in the distribution of the blood. He then continues as follows.]

In cases of arterio-dilatation the powerful irritation of the skin by the ingredients of the water increases the tonus of the arteries by reflex action; whilst in the less frequent cases of vaso-motor spasm the excessive contraction is relaxed, the result of the baths in either case being a tendency to re-establish the normal optimum. The tension of the easily compressible pulse is better after the bath and the blood pressure rises in cases where it was previously abnormally low. On the other hand, there is decrease of blood pressure and of arterial tension when these have been abnormally high. Concomitant with these vascular changes the baths bring about, by reflex action, more vigorous contractions of the heart, the immediate result being more perfect emptying of the cardiac cavities. Thus is induced a gradual diminution of ventricular dilatation, progressing with prolongation of the treatment even to its entire removal. Now, the removal of dilatation is of paramount importance in all heart affections as it follows from the laws of hydraulic pressure that the heart is overstrained proportionately to its dilatation—viz., a pressure acting upon a fluid is distributed equally through the entire amount; if, therefore, the heart contains just so much blood as it ejects normally at each stroke, it need only do so much work as is necessary in order to press its entire contents into the arteries; but should it be dilated and contain more blood it will have to do proportionately more work even to eject only its normal contents, the rest of its labour being wasted on the remaining amount of blood on account of the equal distribution of the pressure of the ventricular walls through the entire amount of blood contained in the ventricles

As already stated, reaction sets in sooner and more perfectly in a Nauheim bath than with ordinary fresh water, and should its temperature be near the "point of indifference" reaction supervenes with rapidity. Such baths have almost solely a relieving influence on the heart The lower the temperature the longer the period which precedes reaction, the cooler baths having therefore a preliminary stimulating effect which we utilise as an exercise for the heart. Thus, by regulating the temperature and also the carbonic acid and saline constituents we can achieve by these baths an exceedingly accurate dosage of relief or exercise for the heart, and the technical arrangements for effecting these gradations are of the most perfect type I know of no other means by which relief and exercise for the heart can be for weeks administered with such absolute precision. It is, however, here expedient to mention that we usually combine the treatment with medico mechanical gymnastics, resistance exercise, massage, and electrical treatment, including the use of the sinusoidal alternating current.

In selecting cases for Nauheim treatment it is important to bear in mind that less depends upon the cause of the disturbed circulation than upon its degree The baths are equally indicated in valvular lesions, in muscular weakness with dilatation, in arterio-sclerosis, and in 'nervous heart complaints so long as the affection is not too far advanced and so long as the heart possesses that necessary amount of reserve-energy through the stimulation of which the power necessary for maintaining the circulation can be restored Competent observers assure us that they have seen the valvular lesions of a recent rheumatic fever disappear through a course of the baths Patients in whom suspicious cardiac signs succeed an attack of rheumatism are suitable cases for Nauheim, and those with valvular defects may with advantage take baths as a prophylactic while in a perfect state of compensation I have seen very favourable effects in such cases where the dilatation underwent a reduction of from one to two inches during the course Nauheim is also suitable for the earlier stages of non compensation with slight dyspnœa during rest or [illegible] of the ankles, and a sma[illegible] In the medium stages [illegible] dyspnœa, œdemata, and albuminuria the results cannot be foretold with certainty Much depends on the patient's age and certain it is that in such cases digitalis gives better results with the baths than without them For the more advanced stages with ascites and anasarca nothing is to be expected from Nauheim treatment Especially favourable for Nauheim are simple muscular weakness and the earlier stages of dilatation such as too commonly supervene on influenza, enteric fever, and acute rheumatism and are so frequently attributable to alcoholic excess, over-exertion, anæmia, and chlorosis Fatty heart accompanying general obesity is, as a rule, favourably influenced by baths, gymnastics, massage, and dietetic regulations, including the use of the water as a beverage *Pari passu* with diminished dilatation we observe increased muscular vigour and loss of weight

As regards arterio sclerosis, it seems reasonable to assume that the resolving action of the mineral baths may have a favourable influence in incipient stages on the process itself. Such early diagnosis is, however, difficult and usually the patients come to Nauheim when such consequences as cardiac weakness and angina pectoris have begun to manifest themselves In not too advanced stages the action of the baths is often very favourable Patients feel considerable relief and the angina frequently vanishes, the effect being doubtless chiefly attributable to the removal of peripheral circulatory resistance As a class these cases require more than ordinary precaution in grading the degree of effervescence In the later stages of the disease this treatment is of no avail. Practical experience of the action of the waters combined with a knowledge of physiology will in most instances enable a correct selection to be made of the cases which are suitable for treatment at Nauheim

Bad Nauheim.

CONTRIBUTIONS TO THE STUDY OF THE ACTION OF SEA-SNAKE VENOMS.[1]

PART I

BY SIR THOMAS R FRASER, M D. EDIN., F.R S.,
PROFESSOR OF MATERIA MEDICA IN THE UNIVERSITY OF EDINBURGH,
AND
R. H ELLIOT, M B LOND., F R C S ENG.,
MAJOR, I M S., ON SPECIAL DUTY FOR SNAKE VENOM RESEARCH UNDER THE ORDERS OF THE SECRETARY OF STATE FOR INDIA
(From the Pharmacology Laboratory of the University of Edinburgh)

THE only important contributions to the literature of the subject with which we are acquainted are those recently made to the Royal Society by Captain Leonard Rogers, I M S Whilst acknowledging the value of these papers we desire to state that our work was planned before we saw them and has in all respects been independent of them

The venoms used in this research were those of two species of sea snakes (1) that of Enhydrina Valakadien (*a*) expressed in Madras by Dr P P Pinto from the venom glands of freshly killed large snakes and sent to us in the dry state, and (*b*) extracted by us from the dried glands of small snakes which had been collected by the same gentleman, and (2) that of Enhydris curtus prepared in the same way as the first mentioned specimen, of which, however, only a small quantity was procured for us by Dr Pinto

The minimum lethal doses of the various specimens of venom—1 (*a*) Expressed Enhydrina Valakadien venom —

M L D for rats = 0·00009 gramme per kilogramme of body weight
" for rabbits = 0·00006 " " " " "
" for cats = 0·0002 " " " " "

The minuteness of these doses proves that sea snake venom is the most lethal of all substances the lethal power of which has been determined

1 (*b*) Enhydrina Valakadien venom extracted by us from dried glands This proved to possess a lethality rather less than half that of the expressed venom

2 Expressed Enhydris curtus venom The minimum lethal dose for rats was between 0·0005 and 0·0006 gramme per kilogramme The minimum lethal doses for rabbits and cats likewise proved to be higher than those of the enhydrina venom We mention this difference in lethality between Enhydrina and Enhydris venoms without laying stress on it, as we are unable to be certain that it was not due to some change which the enhydris venom had undergone

Comparison of the relative lethality of Enhydrina and cobra venoms for various animals—An active specimen of cobra venom was taken, the minimum lethal doses of which for rats, rabbits, and cats had been found to be 0·0005, 0·0006, and 0·010 gramme respectively per kilogramme of body weight of animal Expressing the smallest minimum lethal doses in the case of each venom as the unit we find the relative lethality for the different kinds of animals to be the following —

Cobra venom	rats = 1, rabbits = 1·2, cats = 20.
Enhydrina venom	rabbits = 1, rats = 1·5, cats = 3·3

The difference in the cat rodent relationship is especially suggestive of a marked difference in the physiological actions of the two venoms and the reversal of the rat rabbit relationship is also of some significance in the same connexion

Symptoms of sea-snake poisoning in animals—In the main these symptoms resemble those of cobraism, but the dyspnœa is more urgent, probably because the heart is not directly affected by the venom as it is in cobraism We have observed that lid rise of the lower lid is a constant sign in Enhydrina poisoning, as it is in the course of poisoning by the venom of the cobra and krait It appears to be produced by an elastic rebound of the lid, caused by paralysis of its depressor muscle, probably central in origin, and it is closely comparable with the ptosis met with in cobraised men and monkeys Of the two points dealt with above, the first suggests a difference between the actions of cobra and Enhydrina venoms and the second a resemblance between their actions

Methods of experiment employed—These were · 1 Perfusion of the frog ventricle with solutions of Enhydrina venom. 2. Perfusion of the vessels of pithed frogs with solutions of Enhydrina venom. 3. Kymographic experiments in which the blood pressure, respiratory movements, &c., were recorded and studied both before and after the intravenous injection of Enhydrina venom. The movements of the auricle and ventricle were also studied during life by removing a portion of the chest wall and attaching levers to the heart by hooks and silk threads. Venom was intravenously injected and the results were recorded and noted. 4. The state of the phrenic, sciatic, and vagal nerve ends was studied immediately on the occurrence of death in animals which had received various lethal doses of Enhydrina and Enhydris venoms. The secondary current was used for this purpose and the distance of the secondary from the primary coil, when a muscular contraction was observed, was noted and stated in millimetres. 5. The medulla oblongata of rabbits was exposed and Enhydrina venom was dropped upon the medulla at the region of the respiratory centre. Respiratory movements were recorded on a drum with the aid of a double stethoscope.

---

[1] Abstract of a paper read before the Royal Society on June 9th, 1904.

Summary of results.—1. Enhydrina venom has no direct action on the walls of the arterioles, or at least has no action in any strength of solution which could be present in the blood of a human victim of sea-snake bite.

2. *Enhydrina venom acts directly on the isolated frog* ventricle, producing a tonic and stimulating effect, but this action is produced only by very strong solutions (1 in 5000). The heart beat is quickened and the result is therefore similar to that produced by very weak solutions of cobra venom (1 in 1,000,000 or weaker).

3. By experimenting with the mammalian heart exposed *in situ*, we have clearly shown that Enhydrina venom has no direct action on the vagal cardio-inhibitory centre. This affords a striking contrast to the condition observed in cobra poisoning. In the latter case the powerful tonic and stimulant action of the venom on the heart muscle (or more probably *on its nerve ends*) is masked by equally powerful and direct stimulation of the cardio-inhibitory centre. In Enhydrina poisoning, on the other hand, the complete absence of cardio-inhibition leaves the feeble tonic action on the heart free to manifest itself, as appears to be displayed in several of our tracings. We cannot otherwise explain the increase in rate of the heart beats which we have not infrequently met with in our experiments.

4. Enhydrina venom has apparently no direct action on the vaso-motor centre. Rogers found that on the injection of a viperine venom, or of the venom of the banded krait (Bungarus fasciatus), into an animal a marked fall of blood pressure occurred which was of central origin. In an investigation made by one of us with Dr. W. C. Sillar and Dr. G. S. Carmichael (of the Materia Medica Laboratory, Edinburgh) it was found that a similar and powerful action is exerted by the venom of the common krait (Bungarus cœruleus). The absence of any such action by the venom of Enhydrina is therefore worthy of note.

5. The blood pressure curve in Enhydrina poisoning is a remarkably steady one, provided that moderate doses of venom are given and that care is taken to avoid the injection of large volumes of fluid into the blood-vessels. This is due to the fact that the blood pressure is exposed neither to the influence of the rival forces which act on the heart so strongly in cobraism nor to the direct vaso-motor changes with which we have dealt in the preceding paragraph.

6. The respiratory mechanism is that which is chiefly affected by Enhydrina venom. If large lethal doses are employed, such as Rogers appears to have confined himself to, respiration falls rapidly, and a considerable rise of blood pressure, asphyxial in origin, may precede death. The heart beat then quickly slows and blood pressure falls with corresponding rapidity.

Obviously, these are simply the phenomena of rapid asphyxiation. If, however, smaller doses of venom are employed no marked rise in blood pressure occurs. The ordinary level is maintained until near the occurrence of death; the beat then slows and the blood pressure falls. Here we have an expression of gradual cardiac failure brought about by slowly progressive asphyxiation. The absence in slow Enhydrina poisoning of the large asphyxial rises of pressure, which are so characteristic of the final stages of cobra poisoning, is readily explained by the fact that Enhydrina venom has no direct constrictive action on the walls of the arterioles, such as cobra venom possesses.

7. *As to the part of the respiratory mechanism that is* affected by sea-snake venom, the rapidity with which respiration is affected, both when venom is injected into a vein and also when it is applied directly to the medulla oblongata, leaves no room to doubt that the respiratory centre is directly acted on by the venom. On the other hand, we have shown that some degree of motor nerve-end paresis is constantly present in animals dying from the effects of subcutaneous injections of this venom. We have also emphasised the fact that, in experiments carried out by dropping venom on the exposed medulla oblongata, we have failed to kill animals through the respiratory centre with their motor nerve ends still undamaged. In this respect we have shown that Enhydrina venom differs in its action from cobra venom. It would therefore appear that in poisoning with Enhydrina venom motor nerve-end paresis plays a much greater part than it does in cobraism. It is not difficult to suppose that a blunting of the motor nerve-end mechanism, even though far from absolute, may seriously add to the embarrassment of a centre which has already been directly and gravely enfeebled. We hope to return to this and other points in a future communication.

In conclusion, we desire to express our sense of indebtedness to the India Office, to the Government of India, and last, but by no means least, to the Madras Government, for the assistance and facilities which they have given us in the carrying out of this research.

ON THE ACTION OF THE VENOM OF BUNGARUS CŒRULEUS (THE COMMON KRAIT).[1]

By R. H. ELLIOT, M.B. Lond., F.R.C.S. Eng.,[2]
MAJOR, I.M.S.;

W. C. SILLAR, M.B., B.Sc. Edin.,
LECTURER ON EXPERIMENTAL PHARMACOLOGY AND SENIOR ASSISTANT IN THE MATERIA MEDICA DEPARTMENT, UNIVERSITY OF EDINBURGH;

AND

GEORGE S. CARMICHAEL, M.B., Ch.B. Edin.,
ASSISTANT IN THE MATERIA MEDICA DEPARTMENT, UNIVERSITY OF EDINBURGH.

(From the Pharmacology Laboratory of the University of Edinburgh.)

THE only previously recorded work known to us on this subject was performed by Captain L. Rogers, I.M.S., and his results were publised at the beginning of the present year. Experiments were performed by us in the pharmacological laboratory of the University of Edinburgh with the following results:—

1. We determined the minimum lethal dose of the dried venom for frogs and small mammals, rats and rabbits only being chosen, as our stock of the venom was very limited. We found that the minimum lethal dose for the frog was about 0·0005 of a gramme per kilogramme, for the rat 0·001 gramme per kilogramme, and for the rabbit the remarkably low dose of 0·00008 gramme per kilogramme.

2. We found that Calmette's antivenomous serum in quantities sufficient to protect rats against ten minimum lethal doses of cobra venom in the same quantities was quite powerless to protect these animals from similar doses of krait venom.

3. We studied the condition of various nerve terminals, both in animals that die after poisoning by krait venom and in nerve muscle preparations from the frog, and found that the integrity of these nerve ends was invariably involved at a comparatively early stage in the poisoning.

4. The blood was carefully examined and no evidence of ante-mortem clotting or intravascular hæmolysis was discovered.

5. We examined the action of krait venom when its solution was perfused through the isolated vessels and heart, respectively, of the frog. We found that this venom, while resembling in action that of cobra venom, differs greatly in the degree of constriction of vessels and enhancement of ventricular contraction produced. Cobra venom exercises an action in these directions many times greater than that of krait venom. (Cardio-plethysmographic tracings were shown.)

---

[1] Abstract of a paper read before the Royal Society on June 9th, 1904.

[2] On special duty for snake-venom research, under the orders of the Secretary of State for India.

6 Studying the manner in which the vital functions of mammals (rabbits, cats, and dogs) were influenced when exposed to the action of this venom we found that the vaso-motor centre was strongly affected, a suspension of the activity of this centre, as shown by the great splanchnic dilatation, rapidly ensuing after its transient stimulation There were also indications of a feeble cardio inhibitory action The experiments and illustrative tracings likewise showed that death was brought about by destroying the activity of the respiratory centre (Kymographic and plethysmographic tracings were shown)

7 From these results the conclusion may be arrived at that while the symptoms produced by krait poisoning are similar to those of cobra poisoning, they differ so much in relative degree as to render it doubtful if they can properly be spoken of as identical

A CASE OF CHRONIC STREPTOCOCCUS ENDOCARDITIS TREATED BY SERUM SPECIALLY PREPARED BY USE OF THE ORGANISM OBTAINED FROM THE PATIENT.

By T J HORDER, B Sc, M D, M R C P LOND,

PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL, MEDICAL REGISTRAR AND DEMONSTRATOR OF MORBID ANATOMY AT ST BARTHOLOMEW'S HOSPITAL.

THE success attending the introduction of antitoxic sera into therapeutics led to an expectation that equally good results might follow the use of bactericidal sera As yet, however, these hopes can scarcely be said to be realised. Excluding the cases in which the disease may fairly be claimed to be sapræmic in nature and those in which the bacteriological evidence is absent or incomplete there remain very few, if any, in which the presumption is at all strong that a cure is to be attributed to the use of immune serum Both to the clinician and to the student of immunity the question, How much of the recovery from septicæmia or pyæmia may fairly be credited to the serum used and how much to time and the patient's natural defensive mechanism, is beset with many difficulties But since experience teaches us that in septicæmia a natural cure is rarely to be expected, the results of our researches into immunity being what they are we feel bound to give immunised sera a wide and prolonged trial in cases coming under our care To report only our successes is calculated to give us a false notion of our advance in the matter of serum therapy To report our successes in cases the real nature of which is unknown can only lead to confusion

There is no better instance at the present time of the fact that we can only expect any advance in treatment by using all the available methods which we possess in diagnosis Forgetting this primary principle of our profession, we are prone to rush to the exhibition of a serum as soon as any "septic" case is presented to us On the score of expense alone it is certain that we waste many litres of bactericidal sera, our patients' pockets and our hospital funds being the poorer in consequence But the expense entailed to our methods of practice is much more serious It is time that we stemmed the tide of this indiscriminate serum therapy

The immune serum for which the best results have been claimed in the treatment of disease is the antistreptococcus serum Its failure in many cases may be due to a variety of causes One of these causes, and probably a very important one, may be that the serum employed is not immunised against the particular streptococcus causing the disease but against a different streptococcus This consideration involves the question of the unity of the streptococcus as a pathogenic organism—a question which entails too many matters of a purely bacteriological nature to be entered into here Suffice it to say that streptococci from different sources are often found to show such varied biological characters as to suggest that [illegible] or miss ' character of the remedy.

The ideal serum for the treatment of any particular patient suffering from streptococcus infection must be one obtained by the use of the organism actually causing the disease in that patient, for this serum can alone be guaranteed to be specifically associated with the causal agent of the disease To obtain this ideal serum we have but two alternatives open to us—either we must possess certain trustworthy tests whereby we can recognise the particular streptococcus obtained from the patient, so that we may choose a serum already at hand and produced by the use of that organism, or we must specially prepare the serum by the use of the very streptococcus which we have obtained in the course of our bacteriological diagnosis of the case At present the first alternative is not possible, although we may hope that it will shortly become so. But even when these tests are established we shall have to wait until the various pathological streptococci are subjected to them before we can utilise the right serum, and we shall doubtless now and again encounter an [illegible] um has hitherto been produced [illegible], of preparing a special immune se[illegible] consideration—is only practicable in cases where the duration of the disease extends over at least eight weeks, since this interval would seem to be necessary before the serum of a horse inoculated with a streptococcus is likely to contain anti-bodies of sufficient strength to make it of therapeutic value, nor does there seem at present to be any way of shortening this interval Now cases of general streptococcus infection of sufficiently long duration to promise any success from this method of treatment are not common, yet they exist in fair numbers, especially in the form of ulcerative endocarditis The case reported in this article is an instance, the disease lasted over six months When the nature of the infection was discovered by means of a blood culture the various antistreptococcus sera on the market were tried (Pasteur Institute, Lister Institute, Burroughs, Wellcome, and Co, and Parke, Davis and Co) but without success A specific immunised serum was then obtained from two animals by the use of the patient's particular streptococcus, and this serum was freely used

The case is recorded because I believe it to be the first of its kind, if not the first of any kind, in which treatment has been by serum thus specially prepared Another reason for recording the case is that the treatment formed a somewhat crucial test of bactericidal serum therapy, and its failure makes it highly probable that there are important factors in such cases or in the production of the immune serum of which we are at present quite ignorant Reference will be made later to some of the questions suggested by the case and its treatment

Clinical history of the case —The patient, an unmarried woman, aged 25 years, had been well until August 8th, 1903, when she consulted her medical attendant for shortness of breath and chilliness of the extremities She was somewhat anæmic No heart murmur was heard She was seen from time to time until the 30th, when she was found to be in a very nervous condition, with tachycardia, exophthalmos, marked tremors, anæmia, and a soft blowing bruit in the region of the apex of the heart, well conducted into the axilla There was no thyroid enlargement Graves's disease was diagnosed and the patient was confined to bed The chief complaint at this time was of flying pains in the limbs There was no rise of temperature until Sept 16th, when the thermometer registered 101° F in the evening From this day until the fatal termination of the illness six months later fever was present continuously

On Oct 1st the cardiac bruit was noticed to be much harsher and on the night of the 2nd there was a rigor On [illegible] was [illegible] gors [illegible] ring [illegible] the bruit was noticed The spleen was impalpable, the urine was natural, and there was no œdema A diagnosis of ulcerative endocarditis following on Graves's disease was made. On Nov 10th I saw the patient in consultation with Dr C G B Kempe of Salisbury The diagnosis was confirmed and a blood culture and leucocyte count were carried out On the 17th I saw her again A few small scattered petechiæ had occurred over the neck and the chest, rendering the prognosis more grave

On Jan 6th, 1904, I saw the patient for the third time The petechiæ had increased somewhat in number but were at no time very numerous On Feb 16th Dr. Kempe noted the presence of a soft but distinct murmur over the pulmonary area of the heart with fresh crops of petechiæ On March 7th an attack of dyspnœa, with signs of consolidation at the base of the left lung, suggested the presence of an infarct at this situation. At midday on the 22nd the patient died somewhat suddenly. The total duration of the illness was thus over seven months and the duration of the fever was over six months. The form of the fever for the great part was remittent, the temperature ranging between 101° and 103·5.[1]

The leucocyte count.—On Nov. 10th this was 14,000 per cubic millimetre, and at a second count on Jan. 5th it was 12,000. This absence of a marked leucocytosis is not uncommon in chronic cases of ulcerative endocarditis, even when of streptococcal origin.

The blood culture.—On Nov. 10th five cubic centimetres of blood were withdrawn from a vein of the arm with aseptic precautions and three broth and three sloped agar tubes were inoculated. On the second day growth appeared in the broth and on the agar and this was found to be a streptococcus in short chains. One cubic centimetre of a 24 hours' subculture in broth killed a mouse in two days. Dr. M. H. Gordon had in hand at this time an investigation into the streptococcus group of organisms for the Local Government Board, with the object of obtaining differential tests if such existed and for this purpose he was trying the effect of streptococci on a medium containing one or another of a series of carbohydrates. A number of examples of streptococcus pyogenes tested in this way were found to conform to a definite type. I am indebted to Dr. Gordon for a similar examination of the streptococcus obtained in the blood culture from this patient; the organism was found to show a distinct variation from streptococcus pyogenes. Moreover, the organism was found to change neutral red, a chemical test not yielded by streptococcus pyogenes.[2] Cultures obtained on one occasion only from the patient's throat, though they yielded a variety of streptococci, gave no organism fulfilling the same series of reactions as that obtained from the blood. Nor could I prove on either of two occasions that the streptococcus of the blood was being excreted in the urine.

The serum treatment.—1. Various sera on the market. These were given as soon as the result of the blood culture was known. All the "polyvalent" sera obtainable were given a good trial in turn. After the second dose of Pasteur Institute serum the temperature fell and there was no rise for over 48 hours. This was the only occasion in the course of the illness when the fever abated for more than six hours. But this apparently good result was not maintained even though the dose of serum was much increased. The Lister Institute serum and the sera made by Messrs. Borroughs, Wellcome and Co. and by Messrs. Parke, Davis and Co. produced no result. This treatment was continued for seven weeks. 2. Specially prepared sera. On Jan. 9th Dr. W. Dowson kindly placed a donkey at my disposal at the Wellcome Physiological Research Laboratories, Brockwell Hall, and himself undertook the necessary inoculations. Increasing doses of living cultures of the streptococcus were given at intervals of from one to nine days, followed at the end of eight weeks by two large doses (200 and 250 cubic centimetres) of cultures digested in horse plasma with one week's interval. Following each injection enormous swellings were observed at the seat of inoculation, often involving the whole of one side of the trunk. The animal was bled before the first inoculation and at the end of the first week, as well as on four occasions further on in the process of immunisation. The object of the first two bleedings was to obtain normal serum from the same animal furnishing the immune serum, it being thought advisable to first use this as a control, in case positive results were obtained with the immune serum. Previously to this, however, the patient was injected with 30 cubic centimetres of human serum, obtained by bleeding a brother, as it was possible that the absence of sufficient complement might be in a measure responsible for the protraction of the disease. The injections at this time therefore comprised the following series: normal human serum, normal donkey's serum, immunised donkey's serum removed at intervals up to nine weeks from the beginning of inoculation. The treatment was continued over a period of more than two months, during which time some 550 cubic centimetres of serum were given. The great bulk of the serum was administered subcutaneously or intramuscularly. At no time did the temperature chart suggest that there were any good effects from the treatment.

Shortly after Dr. Dowson had commenced the inoculations at Herne Hill Dr. George Dean of the Lister Institute kindly undertook to treat a horse with the streptococcus with a view to obtaining immune serum. Four injections of 10 cubic centimetres, 20 cubic centimetres, 50 cubic centimetres, and 100 cubic centimetres of living cultures in horse serum bouillon were given, the horse being bled three weeks after the last injection was made. After each dose there was a marked reaction at the seat of inoculation with a rise of temperature. The serum yielded by this horse was likewise given a good trial but with equally disappointing results.

General and drug treatment.—When the nature of the case was established open-air treatment was adopted as far as possible and at one time some benefit appeared to result from this expedient. Besides this and a carefully chosen nourishing diet with stimulants (chiefly as port wine) the following drugs were prescribed: quinine in five-grain doses every four hours, sodium sulphocarbolate up to 15 grains every four hours, and formaldehyde in doses of from two to four minims by the mouth frequently. Each of these drugs was given a full trial in turn.

I have already indicated the main points of interest connected with this case. Not allowing for factors at present unknown to us, the possible explanations of the failure of the serum treatment seem to be these: 1. The infection was a mixed one, the streptococcus only having grown in the blood culture. This I think unlikely. Cases of ulcerative endocarditis due in part or in whole to other organisms than the streptococcus usually run a much more rapidly fatal course. Moreover, this explanation includes the notion that the streptococcus present was little or not at all pathogenic, a notion not supported by general experience or by the animal experiments carried out with the organism. Unfortunately no post-mortem examination could be obtained in order to decide this question. 2. Neither of the sera specially obtained possessed the "immune body," or possessed it in too small a degree to be of service to the patient. If this were so the chance of any serum, not specially obtained, containing the immune body needed for the treatment of a particular case must be much more remote than we at present imagine. 3. The patient's blood was deficient in the "complement" necessary to fix the "immune body." This accident seems to be an unlikely one at any time. But it was with the view of meeting it that the normal human serum was used. It would doubtless have been a reasonable thing to continue the injections of human serum for a longer time than was done. But this treatment is as yet scarcely within the range of practical therapeutics.

Whether the prolonged course of the disease was in any way due to the treatment by serum and, if so, to which serum it was due, are questions that cannot be answered.

In conclusion, I must express my thanks to Dr. Kempe, without whose constant and valuable coöperation the prolonged and systematic treatment could not have been carried out; to Dr. Dowson at the Wellcome Laboratories, who responded most promptly to my suggestion concerning a special serum; to Dr. Dean for similar assistance at the Lister Institute; and to Dr. Gordon for the part of the bacteriological investigation mentioned above.

Harley-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON THE VALUE OF KADER'S OPERATION OF GASTROSTOMY.

BY J. CRAWFORD RENTON, M.D. EDIN.,
SURGEON AND LECTURER ON CLINICAL SURGERY, WESTERN INFIRMARY, GLASGOW; FORMERLY EXAMINER IN SURGERY AND CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH.

HAVING performed this operation four times recently, I think it right to record my satisfaction with it, both as regards rapidity and ease in carrying out the details and its efficiency as a means of feeding the patient and insuring no escape of fluid from the stomach even when coughing.

The usual incision for gastrostomy is made. Having opened the abdomen, four retaining loops of silk are passed

---

[1] As the temperature chart measures some 20 feet in length it cannot be reproduced here.

through the peritoneum and placed equidistantly round the
ig applied to each This
down when the stomach is
mach, as near the cardiac end
as possible are drawn out, the peritoneum and aponeurosis are carefully stitched to the stomach, using a Reverdin's curved needle, the stomach is then opened and a No 12 soft catheter is introduced and fixed in position by a fine suture which passes through the whole thickness of the stomach wall and is tied tightly round the catheter The stomach is now invaginated by pressing upon the firmly secured tube and a purse string suture is introduced a quarter of an inch below the opening into the stomach *This is drawn up and tightened round the tube*, a second purse string suture is introduced half an inch below the *first, the stomach being further invaginated* and the stitches tightened around the tube, a third purse string is introduced half an inch below the second if necessary and tied round the tube In this way a valve is formed inside the stomach so that the tube can be easily passed in and when *removed the valve comes together and completely* closes the opening The skin incision is united with silk worm gut. After the wound is healed the patient soon *learns to feed himself Having first chewed the food he* passes it into the tube which is inserted into the stomach Those interested in this subject will see two good plates illustrating the operation in Kocher's recent work on Operative Surgery translated by Stiles

Glasgow

A CASE OF INJURY TO THE BACK FOLLOWED BY ALL THE APPEARANCES OF SYRINGOMYELIA

BY CHARLES MACKIE BEGG, M B, L R C P EDIN

HOUSE SURGEON BOROUGH HOSPITAL BIRKENHEAD

A MAN aged 37 years was struck on the back by a sack of corn which fell from a height of over 30 feet He was admitted to the Birkenhead Borough Hospital on June 6th the day of the accident. There was severe bruising over the back of the neck and chest No irregularity of the vertebral column could be discovered and there were no symptoms pointing to any injury of the spinal cord The patient was a very powerfully built man and stated that he had previously enjoyed perfect health

Recovery *went on apparently uninterruptedly till June 12th* when he complained of some weakness in the arms and legs On examination the knee jerks were found to be brisk On the 20th th
thenar and
was distinct
was some di
both sides His condition became worse, the spasticity of *his legs increased and the wasting of the muscles of the fore* arms and hands became very marked On the 30th his condition was as follows In the upper extremities there was marked wasting of the small muscles of both hands and of the flexors and to a lesser degree the extensors of the fore arms The pronators and supinators were very slightly if at all affected The biceps triceps and deltoid were slightly wasted but not nearly to the same extent as *the muscles of the forearm* The affected muscles reacted sluggishly to electricity Both biceps and triceps jerks could be elicited There was no impairment of any of the senses in the arms In the lower extremities the muscles were spastic both knee jerks were much increased the ankle and patellar clonus was marked and Babinski's plantar reflex was present in both feet With great difficulty the patient c
hes from the
bed There
on
sensations
to pain was diminished in both legs and the
between heat and cold was not appreciated There was some weakness of the abdominal muscles, the patient being quite unable to sit up in bed The bladder and rectum were unaffected

The further progress of the case was as follows On July 8th the patient could sit up in bed without assistance and his grasp was slightly stronger There was some fibrillary twitching of the tongue and his speech was not so distinct as before There was no improvement in the wasted muscles of the hand

The case
s of
syringomyeli
the
onset and the
sion
was evidently in the seventh and eighth cervical and first
the cause
producing
of the arms
and by its pressure causing
pyramidal tracts? If so the
myelitis must have cut off the
and cold and pain senses from the lower limbs It is possible that the patient may have had a dilatation of the central canal previously This may have caused no symptoms till *the blow on the back* produced effusion or slight hæmorrhage into the cavity

I am indebted to *Dr W R Floyd under whose care* the patient was for permission to use these notes

ST GEORGE'S HOSPITAL

NINE CONSECUTIVE CASES OF PERFORATED GASTRIC ULCER TREATED BY SUTURE IRRIGATION, AND DRAINAGE

(Seven under the care of Mr G R TURNER and two under the care of Mr T CRISP ENGLISH, eight recoveries)

FOR the notes of the cases we are indebted to Mr Crisp English

CASE 1 —The patient, a woman aged 24 years, was admitted to hospital under the care of Mr Turner on Nov 28th, 1900 with the following history At 9 P M on the previous evening she was frightened by a mouse and immediately after was seized with acute epigastric pain followed by vomiting On admission she looked extremely ill and was in great pain The temperature was 99 5° F and the pulse was 120 The abdomen was rigid distended and tympanitic Acute tenderness was present in the epigastrium Liver dulness was absent

Operation —Median laparotomy was performed above the umbilicus Gastric perforation was found on the anterior surface of the greater curvature near the œsophageal end There were much foul fluid and lymph in the peritoneal cavity The perforation was closed and a counter opening was made below the umbilicus Three drainage tubes were inserted On the fourteenth day after operation thrombosis occurred in the left calf, convalescence was otherwise uneventful and the patient went to the Wimbledon Convalescent Home on Jan 9th

CASE 2 —The patient was admitted to hospital under the care of Mr Turner on March 5th, 1901 with a history of *acute abdominal pain for two days* The pain had been sudden in onset and was situated in the epigastrium, the abdomen had become distended and vomiting had occurred twice On admission the patient who was sent by rail about 100 miles to hospital, looked very ill complaining of great pain and thirst the marked abdominal facies was present the temperature was 97° F and the pulse was 130
ntly distended chiefly in the lower
lle, very tender, and rigid Liver
There was moveable dulness in the
flanks

Operation —A median incision was made Intense general
peritonitis was
fluid
and free gas le
a the
anterior surface
end
As the patient's condition was very bad a gauze plug was passed to the perforation and the peritoneal cavity was flushed out with hot saline solution drainage tubes were inserted and the wound was sutured Death occurred a few hours later

Feb. 12th he was a good deal better mentally. He had several attacks of diarrhœa, with intervening constipation, but no blood, pus, or mucus was passed. He was sick after most articles of food now. His temperature was as before. He was treated with high-frequency currents until vomiting returned. On the 29th he was better mentally and was only sick occasionally; he often had diarrhœa. An examination was made under chloroform but nothing definite was felt in the abdomen. He seemed very weak and was losing weight; six pounds were lost in a week.

The patient went on in this condition, gradually getting weaker and thinner, for about a month. The stools were loose and there were occasional diarrhœa and sickness. The abdomen gradually presented more evidence of disease, consisting of slight general distension, some rigidity of the recti, and a feeling of increased resistance or thickening about the intestines, chiefly in the umbilical region. These signs became more marked towards the end. There was no ascites. He was very apathetic and did not complain of anything. It was thought probable that he had some abdominal tuberculous mischief and the use of tuberculin was suggested, but the man seemed too ill for injections to be given. At 6 A.M. on March 27th Dr. Short was called to see him as he had become speechless and pulseless and lay with his legs drawn up slightly groaning. The abdomen was more distended, especially in the epigastric region, and universally tender. It did not move with respiration. There was no shifting dulness in the flanks. The liver dulness had become reduced to one inch instead of three inches as previously. There was no vomiting or diarrhœa. The temperature was 95° and the extremities were cold. In spite of stimulant treatment he did not rally and died at noon.

Necropsy.—At the post-mortem examination the body was found to be much emaciated and the skin was dry and scaly. The heart and lungs were normal except that at the apex of the left lung there was a small radiating scar with slight thickening of the pleura; there was no caseous matter. There was general peritonitis, with universal injection of the intestines, lymph flakes, and soft recent adhesions. The peritoneum contained one and a half pints of semi-purulent fluid. In the small intestines there were numerous ulcers, the ileum. About six of these were — ; three would only just admit a lead pencil and the bowel was dilated above them. Several of the ulcers were very large, up to one inch in breadth. They ran transversely. The edges were thickened and raised, sloping off on the sides. The floor of many of them was dense and firm owing to cicatricial tissue. In some, however, it was very thin and in two a small perforation had occurred. In several a few tubercles were seen in the serous coat in the periphery. The stomach was markedly dilated. The large intestine showed chronic catarrh. The mesentery was thickened; the mesenteric glands were large, red, firm, and in two cases calcified but not caseous. The liver, spleen, kidneys, pancreas, testicles, and brain were practically normal.

Remarks by Dr. MICHELL CLARKE.—On admission there was obviously a slight degree of obstruction and peristaltic movements of the intestine were visible, though not very marked, through the abdominal walls. These symptoms were accompanied by pronounced nervous ones which took a typical hypochondriacal form. A few days after admission the signs of obstruction became less and the peristaltic intestinal movements disappeared, never to return in the further progress of the case. Simultaneously the hypochondriacal symptoms gradually developed, so that for some time the patient could not be considered as mentally sound. The mental symptoms and the appearance of the patient were at this time those of hypochondriacal insanity. Vomiting now returned with pronounced anorexia and considerable persuasion was required to make the patient take his food. At one time it was thought that forced feeding would have to be resorted to.

The vomiting, emaciation, and anorexia, in the subsidence of the more marked intestinal symptoms which were present on admission, might now, perhaps, have been attributed by anyone who saw the patient at this stage for the first time to the nervous condition except for two signs—namely, the constant presence of liquid stools and the gradual appearance and increase of a feeling of thickening or resistance to pressure in the abdomen. Later in the case there was the remarkable clearing up of the mental condition, whilst the signs of abdominal disease became quite evident and unequivocal. The illness was one well illustrating the not infrequent coexistence of abdominal disease with symptoms of hypochondriasis and the very great difficulty there often is in cases of hypochondriasis in which the patient's feelings and thoughts are centred on his stomach in arriving at a positive conclusion as to whether there is or is not some abdominal disease in the background.

Other points of interest are the apparently primary origin of the ulcers, unless indeed, the scar at the apex of the lung represented old healed phthisis, and the strictures and perforation due to tuberculous ulceration.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

Complete Inversion following Traction on the Cord after a Normal Delivery.—Exhibition of Specimens, &c.

A MEETING of this society was held on July 6th, Dr. EDWARD MALINS, the President, being in the chair.

Dr. ROBERT BOXALL recorded a case in which Complete Inversion followed Traction on the Cord after a Normal Delivery in a Young Primipara. The uterus was pushed back into the vagina. An unsuccessful attempt at re-inversion was made within a few hours and again 48 hours after delivery. Some retained portions of placenta and membranes having been removed and the parts cleansed it was decided to defer any further attempt for a few weeks. Douches were used night and morning. Six weeks later the uterus was found to have regained its normal position. It seems probable that this occurred during the third week, as at that time there were a certain amount of abdominal pain, free red discharge, and pyrexia for a few days which could not be otherwise accounted for. The extreme rarity of spontaneous re-inversion and the action of the douche as a factor in causing reposition were remarked upon.—Dr. A. L. GALABIN and Dr. HERBERT R. SPENCER discussed the case and Dr. BOXALL replied.

Dr. A. H. N. LEWERS showed a specimen of Fibroids and Carcinoma of the Body of the Uterus removed by panhysterectomy from a patient 45 years of age. A lump had been noticed in the abdomen for six years. For two years there had been a constant vaginal discharge but no severe loss. Pain in the lower abdomen had been quite a recent symptom. On vaginal examination a blood-stained offensive discharge was seen issuing from the os uteri. The vaginal portion was normal. The sound passed eight inches. At the operation the body was removed with the intention of leaving the cervix but on cutting through the cervix at the level of the internal os malignant growth (which had not previously been suspected) was found in the lumen. The cervix was consequently removed. Dr. Lewers urged the advisability of opening up the body of the uterus immediately after removal in all cases where fibroids existed, for in his experience malignant growth in the endometrium is not very rarely a complication of uterine fibroids.—Dr. SPENCER preferred total hysterectomy to amputation for fibroids.—Dr. AMAND J. MCC. ROUTH did not consider that cancer was relatively so frequent in fibroid uteri as in cases where no fibroids were present. He regarded metrorrhagia after the menopause in a woman known to have had a fibroid as strong presumptive evidence of cancer having developed. In such cases he advocated panhysterectomy.—Dr. GALABIN thought that fibroids predisposed to cancer and that in all cases of fibroids in which continuous or irregular hæmorrhage could not otherwise be cured in a moderate time the uterus ought to be removed.—Dr. MARY A. D. SCHARLIEB regarded panhysterectomy for fibroids as the best operation both for immediate and for remote results.—Dr. LEWERS, in reply, said that he thought it best in operating for fibroids to leave the cervix if healthy at the time of operation.

Dr. A. W. SIKES showed three Skull-caps of Children illustrating Variations of the Posterior Fontanelle.—Dr. BOXALL remarked on the frequency with which deviations from the normal type of posterior fontanelle occurred.

Dr. WALTER W. H. TATE showed a specimen of Fibromyoma associated with Cystic Disease of the same Ovary removed by operation from a patient, 71 years of age. For two years there had been pain and progressive enlargement of the abdomen and occasional vaginal hæmorrhage. The tumour consisted of two distinct parts: a solid portion of the size of a foetal head which appeared to grow in the wall of the cystic tumour and a cystic portion the wall of which was inflamed and lined by lymph The solid portion proved to be a fibromyoma with necrotic changes towards the centre —Mr **ALBAN H G DORAN** referred to a similar case which he had published

Mr **DORAN** and Dr **H WILLIAMSON** showed a specimen of Necrobiotic *Uterus* associated with *Recent Pregnancy* removed from four to five months after delivery from a patient aged 38 years The specimen was discussed by Dr **ROUTH** Mr **A C BUTLER SMYTHE**, and Dr **J S FAIRBAIRN** and Mr **DORAN** replied

Dr **FRANK E TAYLOR** showed a specimen of Fibroma of the Ovary removed by Mr J Bland Sutton from a *sterile married woman aged 50 years who complained of* severe dyspareunia of many
showed no sign of disease
outer pole of the left ovary
densely hard and lobulated
white surface It measured two and one sixth by one and three quarter inches and weighed two and a half ounces —Dr **FAIRBAIRN** agreed that this was probably an example of the rarest form of ovarian fibroma springing from the tunica albuginea and not from the ovarian stroma —The specimen was referred to the pathological committee

Dr **M S PEMBREY** *and* Dr **G BELLINGHAM SMITH** exhibited five Foetal Sacs which had been found free in the abdominal cavity of a rabbit They were seven or eight centimetres in length four or five centimetres in width, and two centimetres in thickness The largest contained four foetuses, the development of which showed that they were at full term The sacs were formed of the foetal membranes thickened by fibrinous exudate, the placenta could be seen but its maternal surface had been covered over by a similar deposit The *amniotic fluid had been absorbed and the foetuses were com*pressed The abdomen of the mother showed well marked signs of former peritonitis but there was no evidence of placental attachment The uterus on careful examination showed evidence of a former rupture in the shape of an old scar at the junction of the two uterine horns The foetuses had evidently been retained for at least eight months before the animal was killed for during the time it was kept in the laboratory it produced four normal litters The rupture was *probably caused by the impaction of the four* foetuses which were found in one sac and which showed signs of torsion The case supports the view of Mr Bland Sutton that such foetal sacs are not due to extra uterine pregnancy but to rupture of the uterus and extrusion of the sacs into the abdominal cavity

---

EDINBURGH MEDICO CHIRURGICAL SOCIETY

Exhibition of Cases — Associated Transposition of Viscera and Cerebral Tumour —Metastatic Gonorrhoeal Conjunctivitis —Suppuration in the Frontal Sinus

A MEETING of this society was held on July 6th, Professor **JOHN CHIENE** the President being in the chair

Mr **H J STILES** showed a girl aged seven years after operation for Cyst of the Mesentery Though chiefly situated in the epigastric region the cyst extended below the left costal margin It was firmly united to the muscular coat of the intestine and was formed of fibrous tissue covered with peritoneum

Dr **EDWIN BRAMWELL** showed a man aged 34 years suffering from Paralysis of Accommodation in the Right Eye neither pupil reacted to light the left contracted fairly well but the right not at all on accommodation A very careful examination had failed to elicit any further evidence of disease The patient had had syphilis six years previously For several years past he had been using the watchmakers eyeglass for six hours a day and always with the right eye The case was of interest in connexion with Edinger s theory of the etiology of tabes dorsalis Edinger supposes that syphilis acts as a predisposing cause and that superadded excessive function determines the special neurons to be affected in different cases

Dr **W ALLAN JAMIESON** showed a case of Hypertrophic Acne Rosacea after treatment The hypertrophied tissue was simply shaved off with a razor under the action of adrenalin and cocaine The result was very satisfactory He also showed a case of Lupus of the Hard Palate treated by Radium The lupus had existed for five years and had involved the nose the upper lip the gums and the hard palate as well as the axilla X ray *treatment* had cured the face and the arm but it had little effect on the palate Radium bromide inclosed in a tube with an aluminium window was applied for 22 hours to the palate with the result that an entire cure followed

Mr **F M CAIRD** showed a man after removal of a large Renal Tumour (nephroma) The patient also suffered from heart disease ascites and bronchitis His condition was very precarious An enormous tumour was enucleated through a lateral incision It was an adrenal tumour which had engulfed the whole of the kidney Mr Caird also showed a woman aged 54 years, after removal of a large Carcinoma of the Transverse Colon under local anaesthesia Bruits were present over every valve of the heart ascites and bronchitis were present as well as diarrhoea and pronounced anaemia A tumour as large as the fist was removed and end to end suture was performed, the patient only experiencing a dragging sensation during the operation There was no evidence of heart failure

Other cases were shown by Mr **J W DOWDEN**, Dr **R A FLEMING** Mr **J M COTTERILL**, and Mr **A A SCOT SKIRVING**

Dr **W G SYM** *showed Axenfeld s instruments* for use in excision of the lacrymal sac and Priestley Smith s balance for testing the points and edges of cataract knives

Sir **THOMAS R FRASER** read notes of a case of Complete Transposition of the Viscera with Cerebral Tumour and other Pathological Conditions He said that already in 1888 he had described such a case discovered during *the life of a female patient who suffered from cardiac* valvular disease The present case, however, differed from *the former in that the malady from which the patient* suffered ended fatally so affording fuller opportunity for the study of the malformation When first admitted to the Edinburgh Royal Infirmary the patient was a well nourished man, aged 24 years, rather stunted in growth (8 stones 7¾ pounds in weight and 4 feet 11 inches in height), with a round bullet shaped head and stolid expression The primary cause of his admission was a long standing pyuria with headache His father died at the age of 72 years from *bronchitis and his mother died from phthisis at the age* of 62 years Three brothers and five sisters were alive and healthy There was no family history of nerve disease nor had the patient suffered from venereal disease He was unmarried and until a few years ago had followed the occupation of an iron moulder, while latterly he had been employed in a warehouse Both occupations necessitated his lifting heavy weights He had not suffered from any serious illness until the present symptoms began to show themselves now several years ago Some eight years previously he had fallen from a swing and had sustained some injury *to the head though the effects* soon wore off His recollection of this injury was very imperfect A supernumerary thumb was present on the right hand springing from the metacarpo phalangeal joint Six metacarpal bones were present in this hand Physical examination showed that there was a transposition of the thoracic and abdominal viscera and the patient himself was aware of his abnormality To determine if the transposition involved the lowest portions of the alimentary canal as well as the higher two pints of warm water were injected into the rectum with the result that the sigmoid flexure became *dull to percussion in the right flank* A presystolic mitral murmur with accentuation and reduplication of the second sound was also discovered and there was congenital loss of the sense of smell This anosmia was a hereditary or *family defect as it was present in the mother* as well as in a brother and two sisters He was again admitted to the Royal Infirmary in January 1904 At this time the sub occipital pain was more severe than formerly and sensations of formication numbness and tingling in the legs were present Tactile sensibility was somewhat blunted over the left side the vision was much impaired so much so that with the left eye ability to distinguish light from darkness alone remained Death took place on the fourteenth day after admission His temperature throughout was always below the normal and before death it was 97°F The post mortem examination confirmed the diagnosis of complete transposition of the viscera The caecum had the foetal characteristics of conical shape and small size and these characteristics were also manifested in the unusual length and upright position of the appendix vermiformis. Pyelitis was also present. In the brain at the level of the lateral ventricle a translucent rounded tumour of about the size of a large marble was found which gave a complete explanation of the symptoms present. The heterotaxy of the viscera involved not only the important organs but also all the underlying organs and structures, as bronchi, blood-vessels, and nerves in the thorax and the pancreas, duodenum, blood-vessels, and nerves in the abdomen. Dr. Richter published in 1884 a collection of 40 cases, of which 24 were examined after death. Of the latter 17 exhibited complete heterotaxy. In only one was the subject left-handed and cardiac lesions existed in six of the 24 examined after death.

Dr. SYM read a report of two cases of Metastatic Gonorrhœal Conjunctivitis. He pointed out that in the gonorrhœal conjunctivitis produced by direct infection the characters were those of an intense purulent ophthalmia with great swelling of the eyelids, affecting one eye at first, with abundant discharge of pus and great danger of severe ulceration of the cornea. In the metastatic form, on the other hand, the discharge was somewhat thin mucoid fluid, there was very little swelling indeed, if any, and the iris or the cornea might be affected, but only to a very unimportant degree relatively; the attack was apt to come on along with joint symptoms and in persons who had been most careful to avoid the risk of direct infection. The first patient was a young man who had acquired gonorrhœa three months previously; he had practically quite recovered under treatment in about two months, but the discharge from the urethra again began, this time spontaneously (it was not a re-infection) and almost at the same time several joints became affected, and well-marked conjunctivitis came on with fairly abundant discharge. There was, however, very little swelling of the tissues; neither was the symptom at all comparable in degree to that present in a case of direct infection. The irides were slightly injected also. The left ankle and wrist were affected by synovitis and to a less degree the right wrist also. There were at the moment no facilities for bacteriological examination. The other patient was a young man whose gonorrhœa (a first attack) was of four weeks' duration; it had been treated from the first and was never very bad. Conjunctivitis had existed for three days before Dr. Sym was consulted and was not severe at all; the discharge contained no pus and there was no great injection of the globe. In two or three days several joints began to be affected one after another. Bacteriological examination showed very few organisms indeed and it was with the greatest difficulty that a few gonococci could be identified. The disease appeared to be rare and in some even of the latest text-books was not mentioned at all. A very useful paper on the subject was read by Dr. van Moll of Amsterdam at the Utrecht meeting of the International Ophthalmological Congress in 1899. He had met with six cases occurring in three individuals; the symptoms observed by him were precisely similar to those now described. He, Parinaud, Morax, Sattler, and Lichtenstein have all had cases in which no gonococci whatever were found; indeed, in this disease, as in rare instances of other forms of conjunctivitis, cases have been examined in which no germs of any kind were discoverable in the discharge. The most probable explanation of the disease was that it was due to the toxins generated by the gonococcus, but another theory, founded upon the frequency with which staphylococci were found, was that the original urethral mischief was due to a mixed infection of gonococci and staphylococci and that the former were unable while the latter were able to penetrate the unbroken epithelial surface. Morax has succeeded in producing a precisely similar form of inflammation by introducing into the conjunctival sac a dead culture of gonococci, a fact which seems strongly to support the toxic theory.

Dr. A. LOGAN TURNER read a paper on the Operative Treatment of Chronic Suppuration in the Frontal Sinus. He said that many operations had been devised but whatever might be the technique of the operation performed there were two principles underlying the various methods of procedure. First, opening the sinus through its anterior wall, curetting the cavity, and draining into the nose—an operation associated with the name of Ogston-Luc; and secondly, obliteration of the sinus by the removal of the anterior bony wall of the cavity only or of its anterior and inferior walls. Evidence was then brought forward to show that opening and draining the sinus constituted in a large number of cases an unsatisfactory procedure. Statistical tables were shown illustrating the failures that had occurred in the hands of different surgeons and a table was given showing how much more frequently death had followed the operation of opening and draining the sinus than when the obliteration method had been carried out. The obliteration operation was then considered and the better results thus obtained were demonstrated. The question of comparative disfigurement in the two operations was discussed and illustrated by results of operative interference. Finally, the Killian operation was described, its merits were discussed, and the hope was expressed that it might be recognised as an improvement in dealing with these cases.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held at the Guildhall, Windsor, on June 29th, Mr. W. B. Holderness, the President, being in the chair.—Mr. W. A. U. Thomson showed an extreme case of Cretinism in a male, aged 19 years, who was the sixth child of a family of ten children, the other nine being healthy. He had the appearance of a backward child seven or eight years of age. The case had been under the care of Mr. Hastings Gilford of Reading.—Dr. F. J. Hathaway showed three cases, one of them being an example of Charcot's Disease of the Knee in a male, aged 50 years. The joint was distended with fluid and well-marked symptoms of locomotor ataxy were present.—Dr. Clive Riviere read a paper on Conditions simulating Pulmonary Tuberculosis in Children. After speaking shortly of acute tuberculosis and tuberculous broncho-pneumonia, Dr. Riviere passed on to consider those varieties of pulmonary fibrosis and bronchiectasis which simulate phthisis in later childhood. Phthisis, he held, was rare in childhood but bronchiectasis and fibrosis were perhaps commoner than was generally admitted. Whooping-cough was the commonest factor in the production of the slighter forms, the cough and bronchitis leading to bronchiectasis which in some instances became permanent. The most marked cases were usually the result of broncho-pneumonia (especially when complicating whooping-cough), croupous pneumonia, or pulmonary collapse. It was the apical cases which tended to simulate phthisis but even the basal cases might give rise to doubt. The prognosis of chronic apical disease in children was remarkably good, partly because a considerable proportion of such cases was not tuberculous.—Dr. Hathaway read notes of a case of Ruptured Tubal Gestation. The patient, who was under the care of Dr. H. Overy, was aged 35 years, had been married 13 years, and had had no children. She had missed her periods for three months and during the last ten days of the pregnancy she had had attacks of bleeding from the vagina with pain in the lower part of the abdomen and back. The onset of violent pain with collapse was quite sudden. Vaginal examination showed the cervix uteri to be soft and the os not dilated. Dr. Hathaway opened the abdomen below the umbilicus and fluid blood was found in the peritoneal cavity. The uterus was enlarged, and attached to the right broad ligament was a mass of the size of a hen's egg which proved to be a typical gestation sac situated in the ampullary portion of the Fallopian tube. The broad ligament was transfixed close to the uterus and securely ligatured in three pieces with silk, then the mass with the ovary was removed, and the uterus and stump of the broad ligament were allowed to drop back into the pelvis. The patient was rather collapsed after the operation but soon rallied satisfactorily and the subsequent progress of the case left nothing to be desired.

OPHTHALMOLOGICAL SOCIETY.—The last ordinary meeting of the session was held on July 9th, Mr. John Tweedy, the President, being in the chair.—Dr. George Coates gave a lantern demonstration on the Pathology of Thrombosis of the Central Vein of the Retina. He showed preparations from five cases. In four of these an organised thrombus was found in the central vein; in three of them complete obliteration of the vein in a portion of its course had occurred from this cause; and in one of them the manner of re-establishment of the lumen by the accession of collaterals from the trabeculæ of the nerve was well shown. In the fourth case canalisation and not obliteration of the thrombus had occurred. In the fifth no thrombus was found, probably because the optic nerve was cut longitudinally in the usual manner and not transversely as was desirable when a lesion of the central vessel was suspected. He also dealt with the changes found in the retinal vessels of these cases—namely, (1) endothelial proliferation; (2) thickening of the connective tissue of the walls; (3) hyaline degeneration (a change superimposed on the last); and (4) secondary thrombosis. Various combinations of these changes might be found both in arteries and veins. The use of Weigert's elastic tissue stain in researches on vessel changes was also illustrated.—Dr. Hermann Knapp (New York) commented on the ophthalmic appearances which were of such great value in prognosis and which could be seen with such remarkable distinctness, such as the white artery with its least little thread of blood, the white retina in its track, and the scotoma [illegible] ld of vision. He recalled an [illegible] ch for a distance equal to [illegible] the disc one vessel showed [illegible] they entirely disappeared, the scotoma vanishing as the retina became red again The consequences of endarteritis supplied one of the most important chapters in ophthalmology and neurology. He was accustomed to warn patients who showed these changes of their liability to apoplexy unless they simplified their mode of life and diet. In one case where the warning was neglected the patient returned in three weeks with right hemiplegia but subsequently recovered and was now living on a spare diet. This applied also to Bright's disease with retinal changes. Meat and alcohol must be avoided.—Card specimens were shown by Mr. R. Marcus Gunn, Dr. R. D. Batten, and Dr. E. J. Smyth.

Reviews and Notices of Books.

A Manual of Medical Jurisprudence, Insanity, and Toxicology. By HENRY C. CHAPMAN, M.D., Professor of Institutes of Medicine and Medical Jurisprudence in the Jefferson Medical College of Philadelphia. Third edition. With 64 Illustrations and 4 Plates in Colours. London, Philadelphia, and New York: W. B. Saunders and Co. 1903. Pp. 329. Price 8*s*.

THIS work is probably better known in America than in England. The fact, however, that this is the third edition since the book was first published in 1892 is sufficient evidence that the efforts of the author have met with due appreciation. Dr. Chapman, as "coroner's physician of the city of Philadelphia," has had a large practical experience in forensic medicine and is therefore able to refer to many cases which have come under his own observation. He has also the power to express his opinions in a brief but lucid manner, so that although the manual is not a large one nevertheless it contains all the main facts of which it is essential that a student should be aware when presenting himself for examination. In describing the method of conducting post-mortem examinations in medico-legal cases Dr. C[illegible] on the importance of establish-[illegible] glect of such a precaution has [illegible] legal difficulties. The remarks on "identification" are too curtailed and might well be *amplified in future editions.* The chapter on the examination of blood stains contains a full description of the technique which should be employed in order to ascertain whether certain stains are due to blood or to some other fluid. The attempt to distinguish between human blood and that of some animal is generally attended with failure but Dr. Chapman refers to the "serum test" which has recently been suggested. We agree *with his conclusion that it is* doubtful whether even the presence of blood could be satisfactorily established by the "precipitum" test with the kind of material suspected to be blood that is usually submitted to the medical expert for examination, and in the event of that test proving the presence of blood it is still more doubtful whether the differentiation between animal and human blood could be *established to the satisfaction* of the court.

The medico-legal aspects of wounds, burns, scalds, cold, and starvation are all briefly considered, as are also the other subjects which must of necessity find a place in a text-book on medical jurisprudence. Dr. Chapman properly considers that the subject of insanity has so extensive a range as to render it impossible within the limits of a small work to do more than to indicate its salient features and to dwell more especially on those points which particularly come under the notice of the medical jurist. The portion of the book dealing with toxicology gives a description of those poisons most frequently met with. If an account of the rarer ones is required it would be necessary to refer to one of the larger works dealing with this subject.

As a small treatise on medical jurisprudence Dr. Chapman's *manual may be favourably recommended. It is in no* sense a "cram-book," neither does it contain such detailed descriptions or discussions as are to be found in the more elaborate publications, but a much larger amount of information is contained in it than would appear by a cursory glance through its pages

---

System of Physiologic Therapeutics. Edited by SOLOMON SOLIS COHEN, M.D. Vol. VII.: Mechanotherapy and Physical Education. With 229 Illustrations. London: Rebman, Limited 1904. Pp. 420. Price 12*s*. 6*d*.

THE present volume, the seventh of that excellent therapeutic series which is under the general editorship of Dr. S. S. Cohen, *is concerned with a branch of therapeutics for* which it is difficult to find an adequate title. Perhaps it would have been impossible to find a better title than the one which has been adopted—namely, "Mechanotherapy and Physical Education" At any rate, this description conveys the suggestion which is required by the character of the work—namely, that the medical treatment described is in no way concerned with drugs and that the surgical treatment is unconnected with the knife.

As would naturally be expected, a very considerable part of this volume is devoted to the subject of massage, its principles, methods, and applications, and this part of the work, which represents about a quarter of the whole volume, is from the pen of Dr. S. K. Mitchell who, as lecturer on massage in the Philadelphia Orthopædic Hospital and Infirmary for Nervous Diseases, has had wide practical experience of his subject In the wording of the directions supplied for carrying out the various forms of massage no trouble has been spared to insure simplicity and exactness of statement and there is hardly a phase in the manipulative procedure which is not further elucidated by excellent illustrations. It is impossible in a short account of this contribution to do justice to the thoroughness with which the work has been completed or to indicate the large amount of ground covered. Dr. Mitchell is naturally an enthusiast with regard to this physical method of therapeusis. We cannot help thinking, however, that his readers will be disappointed *if they expect* always to meet with the success which it would be gathered from reading his account is to be anticipated from the skilful application of even the best methods of massage. In the second section, written by Dr. Mitchell, exercise as a remedial measure is described; from the practitioner's point of view this part of the book will be found particularly valuable for the purposes of reference, for all the *better known* methods are described and their advantages and disadvantages are reviewed, while the diseases which are benefited by particular systems of exercise are arranged in a sufficiently methodical manner.

To the second half of the volume Dr. L. H. Gulick has contributed a brilliant, though somewhat theoretical, article on Physical Education. He treats the whole subject on the broadest basis *and on* philosophical lines. He insists from a consideration of our ancestral history and of the conditions of our present environment that exercise is necessary for our health and for our comfort. He further insists that the whole tendency of modern civilisation is to deprive us of inducement to exercise our muscles and to substitute temptations for the expenditure of nervous energy. "The conditions of human life," he says, "in civilised countries have changed more since the development of the steam-engine than they had for thousands of years previously." Again, recognising the fundamental truth that form depends on function, he points out the very serious consequences which this deprivation of exercise has had, and is having, on the physical structure of our bodies. Passing from the general to the particular, Dr. Gulick describes how the physical development of our bodies may best be attained and what exercises to employ to secure the best results. The whole of this article is, indeed, well worth reading. More practical, but hardly so interesting, are the chapters by Dr. J. K. Young on Orthopædic Apparatus, by Dr. H. A. Wilson on Corrective Manipulation in Orthopædic Surgery, with a well-illustrated account of Lorenz's bloodless method of reduction of congenitally dislocated hips, and by Dr. Walter L. Pyle on the Physical Methods employed in Ophthalmic Therapeutics. The last-named article is exceedingly well done and it is very suggestive of the advantages which properly adjusted exercises may confer on the development of the eye in its normal function and consequently on its structural formation. The correction of squint by stereoscopic exercises without surgical interference is, indeed, one of the striking examples of the success of mechanical methods as opposed to ordinary cutting operation. The many new mechanical methods, of which this is but a single example, which have recently swelled our list of therapeutic measures justify the publication of a volume on the subject of treatment without drugs or the knife.

Guide to the Analysis of Potable Spirits. By S. ARCHIBALD VASEY, F.I.C., F.C.S., &c. London: Baillière, Tindall, and Cox. 1904. Pp. vii.-87. Price 3*s.* 6*d.* net.

THIS work comprises within a small compass all the essentials connected with the analysis of spirits and shows how from the results obtained the analyst may deduce an idea as to the origin of any sample which he examines. The book is divided into ten chapters and an appendix the first and second chapters and the last deal with generalisations.

Chapter III. deals with Methods of Analysis and these, generally speaking, are based upon the French official methods, which it is pointed out are not always beyond scientific reproach although most of the work which has been done upon the subject has been executed by Frenchmen according to French official methods and published in the French language. So many analyses of potable spirits have been published that there is at the present time very little trouble in finding out whether a spirit is *not* that which it purports to be, though, on the other hand, it is possible that the more astute dishonest dealer may so "doctor" his spirit as to make it conform to *analytical* standards. Chapter IV. is concerned with the Estimation of Aldehydes and Acids and on p. 31 undoubted preference is given to Rocque's method of making up the standard solution of the former by means of aldehyde ammonia. Mr. Vasey recommends the separate titration of the fixed and volatile acidity in view of the fact that the whole original acidity of a spirit must be due to volatile acid. In Chapter V. the author considers the Estimation of the Higher Alcohols and here he has to decide between the various processes which have been described. On the one hand, there are the superior scientific claims of the Dupré-Marquardt-Allen process; while on the other, there is the official recognition in certain countries of the Röse-Herzfeld method and of the method of colouration with strong sulphuric acid. The last method has, at any rate, the advantage that results obtained by it can be compared directly with the numerous French analyses at our disposal. Respecting compound ethers, the estimation of which is treated of in Chapter VI., the interfering effect of aldehydes is mentioned; this may doubtless be a disturbing influence in some spirits—notably in "marc" brandies—but may usually be disregarded. One advantage of the latter procedure is that comparison can then be directly made with most of the French analytical results. In Chapter VII. the Estimation of Furfural is described at some length and Chapter VIII. deals with the Importance of Taste. This chapter is less technical than the rest and the analyst is recommended to cultivate his senses of taste and smell. There is no doubt that expert tasters can detect admixture of spirit from different sources which would escape the average consumer. If the analyst can add to his chemical attainments some of the knowledge of a spirit connoisseur he will make himself an even greater terror to evildoers than he is at present. A description of colorimeters and a collection of spirit analyses occur at the end of the book. In Chapters I., II., and IX. the author expresses his belief in the possibility of judging of the origin of a spirit by the estimation of the bye-products; he is an equally firm believer in the propriety of a purchaser being supplied with that for which he asks.

The book will we think prove of interest to all those concerned in the analysis of spirits.

Précis des Maladies des Enfants. (Compendium of the Diseases of Children.) By Dr. L. BAUMEL. Paris: F. R. de Rudeval. 1904. Pp. 606. Price 8 francs.

THIS volume is one of a medical series which is now being published in Paris under the title of "La Bibliothèque des Précis de Médecine." It is, however, underrating the scope of Dr. Baumel's book to regard it simply as a compendium, for while it can hardly claim to be considered as a text-book it is in many respects much more than what is usually understood by a "précis." It consists of 600 pages of closely printed matter and contains a few illustrations, charts, and diagrams. The general character of the work is clinical rather than scientific or theoretical. There is little recognition of extraneous authority, especially that of English and American origin, and there is a considerable amount of originality. Dr. Baumel is clearly not afraid of his own shadow and he expresses views on the etiology and pathology of chorea, epilepsy, and certain other conditions which, to say the least, are refreshingly unconventional. The original manner in which he views many of the commonplace accidents of childhood renders his book far more interesting reading than is usually the case with works which are of the nature of systematic compendiums. Although it is perhaps hardly fair to the author to say that he is faddy on certain points we may at least without disrespect suggest that he has very strong views on certain subjects—to wit, the pathological disturbances which are referable to dentition and the value of the incubator for the rearing of delicate infants. As regards the use of the incubator the author is of the opinion that the majority of congenitally weak infants (*faiblesse congénitale*)—a class of infants in whom he evidently takes the greatest interest—could be saved if they were kept warm in incubators and fed properly by the breast. There can be no doubt that the thermotaxic centres of the modern infant are quite incapable of maintaining the bodily temperature under the slightest condition of cold—a fact which is abundantly shown by the frequency with which cold feet complicate the difficulties of treating most cases of congenital or acquired "feebleness of infants," so that we cannot help thinking that Dr. Baumel is serving the cause of the infant by demanding in a manner which some readers may regard as unnecessarily insistent that the temperature of the infant shall be maintained at all costs—by incubation *if no other means secure this end.*

In the first chapter, which treats of the general hygienic management of infants, there are several points which naturally strike the English reader as a little behind the times—for instance, it is surely an abuse of terms to describe milk which has been sterilised and diluted with water as humanised milk (“*lait maternisé*”). On p. 13 appears a weight chart of an infant fed for some months on the breast and then transferred to the artificial substitute; the sudden fall in weight and its continued retrogression are very suggestive of the inappropriateness of the title “*maternisé*” for milk of this kind and yet this is practically the only suggestion for the artificial feeding of infants which appears in this volume.

In Chapter IV. (Part I.), a section which describes hæmophilia and Barlow's disease, there are one or two points which confirm our general suspicion that the nature of these diseases is very little appreciated by French physicians. The classification seems altogether confused in this volume. Barlow's *disease, which we in this country consider so peculiarly* amenable to treatment, is spoken of as a very dangerous condition and Henoch's purpura is either not mentioned or is described under the heading of Werlhof's disease. Again, in the section which deals with rheumatism, while the joint manifestations and the ordinary acute variety are fully described, the more ordinary phenomena of the “status rheumaticus” to which we in this country attach so much importance are only incidentally referred to in scattered portions of the text. The chapter on Dentition we regard as one of the best, as it is certainly one of the most original. This so-called physiological process is made responsible for a large number of what are usually regarded as independent accidents—chorea, for instance—but, taken as a whole, we regard this volume as well worth reading.

Clinical Lectures and Essays on Abdominal and other Subjects. By H. D. ROLLESTON, M.A., M.D. Cantab., F.R.C.P. Lond., Physician to St. George's Hospital, &c. With illustrations. London: Sidney Appleton. 1904. Pp. 178. Price 5s.

Dr. Rolleston may be congratulated on the production of a book extremely convenient in form and interesting in contents. None of the chapters are long, the subjects dealt with are very diverse, the manner of writing is clear and brief, and the matter chosen is either interesting from the rarity of the cases discussed or else of great moment from their commonness. The subjects of most importance include ascites, gastric ulcer, and typhoid fever. The interesting rarities are Recklinghausen's disease, persistent hereditary œdema, and progressive myositis ossificans. That Dr. Rolleston is thoroughly at home in the discussion of the etiology and pathology of these unusual conditions everyone familiar with his pathological work will readily understand. In dealing with the more common conditions above mentioned Dr. Rolleston has wisely adopted a practical point of view and offers several suggestions as to treatment which if not always in accord with the usually adopted routine have *the advantage of being at any rate founded on reflective and* logical reasoning. In the management of cases of gastric ulcer he is emphatic on the importance of the state of the mouth and on the possible harm from allowing even plain water by the mouth. Similarly in the case of typhoid fever Dr. Rolleston supports a starvation policy during the height of the fever, allowing, that is, only plain water in considerable quantities by the mouth. He “distrusts the value of alcohol in large quantities” and believes in the hypodermic use of strychnine and in the adminis*tration of small doses of liquor hydrargyri perchloridi.* Dr. Rolleston wisely recommends, however, that an open mind should be kept in the treatment of cases of typhoid *fever, and considers that a routine system is inadmissible,* seeing that the patient and not the disease should be especially the object of attention. Space forbids us to discuss the author's recommendations with regard to vomiting in diphtheria and in cases of gastric ulcer, tapping for ascites, and many other important points, but we can cordially recommend to students and practitioners the perusal of this little work as an easy road to some sound knowledge.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, F.R.S., and J. N. LANGLEY, F.R.S. Vol. XXXI., Nos. 3 and 4. London: C. J. Clay and Son. June 30th, 1904. Price 8s.—These numbers contain the following articles: 1. Some Researches on the Autolytic Degradation of Tissues, Part I, by Janet E. Lane-Claypon (Mabel Webb research scholar) and S. B. Schryver. The authors of this article find that there is a large degradation of tissue shown by the increase in the nitrogenous extractives in all tissue hitherto investigated during the first 24 hours of incubation, amounting in the case of the liver to more than 50 per cent of the total in many instances. Three stages are as a rule observable—a latent or very gradual period, a period of rapid disintegration, and a period of slower but uniform autolysis. As neither perfusion nor ammonium oxalate affects it and as it is not influenced by the substitution of saline for distilled water it is probably a pure chemical function of the cell protoplasm. It is greater in *a fasting than in a well-fed animal. Comparing this* degradation with the action of trypsin on the liver, the authors arrive at the conclusion that the organ (liver or kidney) of the fasting animal contains a larger amount of either enzyme or zymogen which acts as a protection against starvation. 2. On the Secretion of Acid by the Kidney, by Arthur A. Cushny, M.D. 3. Studies on the Maintenance of the Equilibrium of Motion and its Disturbances, so-called “Forced Movements,” by L. J. J. Muskens, M.D. Amsterdam. The author discusses the causes of “rolling movement” and “circus movement” both in invertebrata and in various vertebrates. 4. On the Relationship of the Thymus to the Sexual Organs, by James Henderson, M.R.C.V.S. The author states that castration causes a persistent growth and a retarded atrophy of the thymus gland in cattle, guinea-pigs, and rabbits. In bulls and unspayed heifers the normal atrophy of the thymus which begins after puberty is greatly accelerated, providing that the bulls have been used for breeding and when the heifers have been pregnant for several months. 5. The Composition of Pancreatic Juice, by Lucian A. E. de Zilwa, B.Sc.Lond. 6. A Pseudaffective Reflex and its Spinal Path, by R. S. Woodworth, Ph.D., and C. S. Sherrington, M.D.Cantab., with 12 figures in the text. 7. On the Question of Commissural Fibres between Nerve Cells having the same Function and situated in the same Sympathetic Ganglion and on the Function of Post-ganglionic Nerve Plexuses, by J. N. Langley, F.R.S., with two figures in the text. 8. The Innervation of the Sphincters and Musculature of the *Stomach, by W. Page May, M.D.Lond., with six figures in* the text. The author of this communication finds that the vagus contains easily demonstrable motor and inhibitory fibres for the musculature of the stomach. The splanchnics, on the other hand, have no influence upon the gastric musculature. The effect of stimulation of the vagus on the musculature as well as on the sphincters is first inhibitory and then augmentative. 9. Antiperistalsis and other Muscular Activities of the Colon, by T. R. Elliott, M.A., and E. Barclay-Smith, M.D.Cantab., with five figures in the text. *These numbers also contain the Proceedings of the Physiological Society for March 19th and May 21st, 1904.*

application of remedies to the human body. We may conclude by saying that we have the highest appreciation of the work that is being done under the auspices of the Fund. We hope that it will be fruitful in results. His Majesty the KING has again given proof of the great interest which he feels in the matter by sanctioning the addition of the word Imperial to the title of the Fund which therefore in future will be known as the Imperial Cancer Research Fund.

Health and Education.

THE reception by Lord LONDONDERRY of the great deputation that waited upon him on Monday, in order to present a petition as to the teaching of hygiene which had been signed by nearly 15,000 medical practitioners and to enforce its recommendations by argument, is an event of good augury to the profession. It seems to indicate the approach of a time when medical men, as practically the sole custodians of forms of knowledge essential to the public weal, will not only assert their claim to be heard with deference and attention upon many subjects of importance which for the present are mainly left under the sway of ignorance, but when this claim will be freely admitted by responsible statesmen and will be rendered operative in the departments of public activity which they control. The petition itself was couched in terms so wide as almost to elude controversy and set forth that the petitioners, having constantly before them the serious physical and moral conditions of degeneracy and disease resulting from the neglect and infraction of the elementary laws of hygiene, urged the central educational authorities of the kingdom to consider whether it would not be possible to include in the curricula of the public elementary schools, and to encourage in secondary schools, such teaching as may, without developing any tendency to dwell on what is unwholesome, lead all the children to appreciate at their true value healthful bodily conditions as regards cleanliness, pure air, food, and drink. The petitioners admit that pupils may now receive teaching on the laws of health by means of subjects almost invariably placed upon the optional code, but to this system they demur as being at least inadequate. They maintain that the teaching should be compulsory and that it should be given at a much earlier stage than at present and they append to the actual petition a few paragraphs describing what is now done in the indicated direction in our own army schools, in several of the colonies, and in some foreign countries. Finally, having regard to the fact that much of the degeneracy, disease, and accident with which medical men are called upon to deal is directly or indirectly due to the use of alcohol, and that a widespread ignorance prevails concerning not only the nature and properties of this substance but also its effects on the body and the mind, they urge upon the authorities the importance of including in the simple hygienic teaching sought for elementary instruction at an early stage on the nature and effects of alcohol. The recommendations of the petition, as will be seen from our report, were strongly pressed upon the attention of Lord LONDONDERRY by Dr. R. FARQUHARSON, M.P., Sir WILLIAM BROADBENT, the President of the British Medical Association, and others.

Lord LONDONDERRY, after an appreciative reference to the tone of the petition and to the character of the deputation presenting it, and after expressing the desire of the department under his control to do whatever might be possible in the directions indicated by the petitioners, made an interesting reference to the question of physical degeneracy. He did not know, he said, whether the petitioners as a profession were prepared to affirm the opinion held in some quarters that there is a serious decline in the physical powers of the people, and, if there were such a decline, he feared that it would be impossible for the Board of Education alone to arrest it. But it was the fact that a competent committee had for some months past been investigating the alleged facts as to physical deterioration and he had every reason to think that the conclusions and advice of that committee might be available at no distant date. If it should prove to be the case that such deterioration as might exist was confined to certain sections of the population and was distinctly traceable to certain social or economical conditions, even then, although the work of the schools might do something, the Board of Education would require the coöperation of other agencies in order to bring about a remedy. The safe rule never to prophesy unless you know is one that is early grasped by everyone who is intrusted with ministerial responsibilities; we are therefore not without hope that the extent of the alleged degeneracy has been at least somewhat exaggerated by alarmists. We do not on this account, however, regard the position of the petitioners as being weakened in the slightest degree. For more than 30 years the country has been spending enormous sums of money upon schools and the control of this expenditure has frequently been vested in persons not possessing any discoverable qualification for the proper discharge of the duties committed to them. The general result has been that the children have been crying for bread and we have given them a stone. They have had schooling instead of education and the schooling has closely conformed to the terms of the general confession in the Liturgy. It has left undone nearly everything which it ought to have done and it has done a great many things which it might with advantage have omitted. It has not guided the average working-class boy towards the acquirement of a useful industry or towards a proper appreciation of his duties as a citizen of a great empire. It has not given the working-class girl an inkling of the duties of wifehood or of maternity. Its faults have been largely due to the popular election of local school authorities and to the piteous striving of the baser sort of politicians to please the most ignorant and the least estimable of their constituents. The medical profession has now made an effort to lift the whole question on to a higher plane, to declare *ex cathedrâ* what it is that the children want and in what manner their wants can be most effectively supplied. We trust that the better class of public opinion will before long be enlisted on the side of knowledge against ignorance.

Lord LONDONDERRY called attention to the difficulty arising from the fact that at present there is not an adequate supply of teachers qualified to impart the instruction asked for by the petitioners, but held out hope that this difficulty was in process of being overcome. It does not arise for the first time, for it will be remembered that when the first Adulteration Acts became law there were not analysts enough to carry out their provisions. Even when the teachers are provided it will be necessary to avoid cherishing undue expectations as to the immediate results of their work. They will have to begin at the very beginning and more than one generation must be expected to pass away before any fruit of their labours becomes apparent; before the working classes are more cleanly in their persons, their dress, and their habitations; and before knowledge and appreciation of domestic comfort are at all extensively diffused. Underlying the educational problem we have the still more serious and pressing one of housing; until the wage-earners can obtain better and cheaper habitations than are now usually accessible to them even a sound theoretical knowledge of the laws of health would have to fight against terrible disadvantages. The same consideration applies to teaching about the effects of alcohol. Even when all illusions concerning its food value have disappeared the labouring man or woman will still know by experience that it affords at least a temporary relief from the pains of indigestion or a temporary forgetfulness of the ills of poverty. The way in which it has been singled out by the petitioners gives some colour to the suggestion that he movement as a whole has been captured by teetotalers anc that it may be in some danger of being injured by exagg ation. That this danger is not visionary is sufficiently shown b the example of the United States, where a teetotal organisati has mastered the educational authority and has been al to force upon the schools so-called hygienic text-books wi are only teetotal pamphlets in disguise and which have npelled instructed physiologists to refuse to take part in hing which they cannot recognise as being under the g ance of facts. A very instructive report on this subjec l on American hygienic teaching generally, prepared by s ALICE RAVENHILL, was published two or three years by the Sanitary Institute of Great Britain.

Deaths in Childbe a Preventable Mortal

THE important question of the mo that has long occupied the minds of childbed is one concerned with the care of parturient those who are It is a mortality which is the more to bing-in women. been shown by the results obtained in lying-red as it has almost entirely preventable. Well may we as itals to be why has it not been prevented in private pris be so, same extent? It is high time that some serio the should be made by the legislature, the medical p-upt and all concerned to put an end to such a painful s, of lives, a sacrifice which is the more terrible whe realise that some 4000 women die annually in England Wales in childbed, about half the number falling victims the ravages of puerperal fever. Dr. W. WILLIAMS has done well to devote the Milroy lectures to a consideration of the various factors concerned in producing this serious mortality. It is important in comparing statistics of the mortality in childbirth during the last 50 years to bear in mind the fact that since 1881 the registration of this form of death has been much more satisfactory than previously, but allowing for previous fallacy from this source there is no escaping the fact, as Dr. WILLIAMS *points out, that during the last* 40 years upwards of 40 per cent. of the total childbed mortality has been due to septic diseases. Further than this, this undiminished rate of mortality has been sustained for a period of 20 years and the sources of fallacy are not confined to one or two years. It is possible, of course, that this undiminished mortality is the direct result of the improved certification of the causes of death and is more apparent than real. At the same time there can be *no doubt that the death-rate from such diseases in lying-in hospitals* has been reduced almost to the vanishing point and therefore the undiminished mortality rate must be due to deaths occurring outside these institutions—viz., in private practice.

An examination of the figures for the different groups of registration counties shows that the death-rate from puerperal septic diseases is highest in the hilly districts of the counties lying west of a line drawn from the mouth of the Severn to that of the Tees. A further examination of the results for the Welsh counties undertaken by Dr. WILLIAMS tends to show that, while the mortality from puerperal fever and the accidents of childbirth is excessively high in both North and South Wales, density of population does not seem to be a factor of much importance. On the contrary, the mortality from puerperal fever and from the accidents of childbed shows a marked tendency to prevail in those counties which have in common the features that they are mountainous, hilly, and sparsely populated, and that therefore locomotion is difficult and medical assistance is not easy to obtain. A more detailed investigation of the registration county of Glamorganshire, which is partly composed of mining districts and partly of agricultural areas, leads to the conclusion that puerperal fever often, though by no means always, selects for its ravages the most insanitary districts, while in the densely populated mining districts the mortality from both the accidents of childbed and puerperal fever is very high indeed. What possible explanation is forthcoming of this high mortality? Dr. WILLIAMS is inclined to take the view that while part of it is to be explained by the large number of untrained women who practise as midwives in these districts and the difficulties of obtaining skilled medical assistance, yet that the exceedingly hard lot of many of these poor women is an additional reason why they are unable to resist the inroads of the disease when they are exposed to its infection. An investigation of the mortality rates from puerperal infection and from the accidents of childbirth in many of the large towns and industrial and mining centres in England and Wales tends to show that the same high rates prevail in most of the mining and industrial centres. What are the other causes which can account for this excessive mortality e? Is it due to ignorant midwives? Is it due to the ct of aseptic and antiseptic precautions on the part of ttending these women? Or is it due to unnecessary b ce with the *normal course of labour? Dr.* WILLIAMS wi hesitation in coming to the conclusion that mid- susta most important part in the causation of this acciden lity rate from puerperal sepsis and from the dbirth. With what safety women can be attended by skilled midwives is admirably illustrated by the statistics furnished in the lectures of the results obtained in the extern maternity department of the General Lying-in Hospital where in 23 years (1880–1902) there were 29,346 deliveries and only three deaths, or a mortality rate of 1 in 10,000. If the happy day ever arrives when all midwives are properly trained and sufficiently skilled there is no reason why equally good results should not be obtained throughout the country.

If we admit that the cause of the present high mortality is mainly the untrained midwife we must ascertain our duty in the matter. This is by no means a new question but is one which has troubled the minds of thinking men for many years. It is by an extension of the methods which have answered so admirably in the case of lying-in hospitals that we must try to find an answer to the problem. In other words the solution lies in the better training of medical practitioners and of midwives, but especially of the latter. But how is the efficient training of midwives to be insured? The new Midwives Act doubtless represents an endeavour to deal with the matter although it contains no hint as to how the desirable end is to be obtained. Indeed, recent proceedings of the Central Midwives Board would seem to indicate that the only real source of training, instruction, and supervision—that to be derived from the medical profession—is to be minimised if not ignored. And where are the funds for the proper training of these women to come from? Will they be provided by the charitable public? It must be remembered that in foreign countries such training is provided free by the State. In this country we can only depend on the hope that private and public benevolence will as usual come to the rescue and provide the funds required for the purpose of supplying women with the necessary training. Dr. WILLIAMS's own suggestion is that a National Council should be formed for the purpose of undertaking the proper distribution of trained midwives throughout the country districts and of collecting funds. It should, he thinks, help to found training scholarships, to give grants to districts too poor to support a midwife, and to start a national training hospital for midwives. It is possible that in the course of time the necessary training, which may well be, as it has been, termed of a technical nature, will be taken up by the various county councils and similar public bodies. The Glamorganshire county council is already undertaking something of the kind and it is to be hoped that other county councils will follow its good example. In the meantime the Milroy lecturer has done well in again calling attention to the deplorable sacrifice of valuable lives which still occurs and his eloquent facts and figures will encourage a hope in the minds of our readers that the Midwives Act *if only it can be properly and efficiently carried out* may prove a blessing to thousands of poor women in country districts. It is sad to think that a work which is essentially on affecting the State as a whole will be handicapped want of sufficient funds to carry it out. Surely he something which should appeal to the thousands of mothers who have the inestimable benefits of medical attendance and of first-rate nursing in th he their travail. We cannot believe that they wi needs of their poorer sisters and we hope that a day may at last come when the present deplorable mortality from a preventable disease such as puerperal fever will no longer exist as a lasting disgrace to our boasted twentieth century civilisation.

Annotations.

"Ne quid nimis."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE most remarkable feature of the recent election of three members of the Council of the Royal College of Surgeons of England was the heavy poll. We complained in a recent issue of THE LANCET that the Fellows seemed hardly to appreciate the privileges which they possess, for at last year's election only about half of the Fellows exercised their right of voting, but we must confess that at this election the Fellows have by no means been backward in recording their votes. There are on the register of Fellows 1302 names; of these 182 Fellows are abroad, in the colonies, or serving in the navy, army, or Indian medical services, the addresses of 15 Fellows are unknown, and one Fellow is not yet entitled to vote, so that there remain only 1104 available voters, and of these 819 recorded their votes; this gives a percentage of over 74 and there are few electoral bodies which could sh a higher percentage of votes than this. For the R al College of Surgeons itself it establishes a record whi will not soon be beaten. The highest number of Fellov voting at any previous election was in 1901 when 768 vot papers were received. As is now the rule, very few F ws voted personally, for only 16 attended for this purpo The result of the election differed slightly from the fo ast which we had made, though we had predicted the urn of Mr. H. Gilbert Barling of Birmingham and had ggested that Mr. A. A. Bowlby would very probably prov ccessful. We congratulate Mr. Frederic S. Eve on his tion and feel sure that he will worthily represent important medical school with which he is connec We must, however, express our surprise and regre at Mr. C. H. Golding-Bird was not successful. should have thought that such a medical school uy's could have made Mr. Golding-Bird's election cer We may, however, express our sincere hope that he ove successful at the election next year—for we trust he will then again offer himself as a candidate for t ffrages of the Fellows. As on former occasions th ere many plumping votes. The largest number of were given to Mr. Eve who received 53 plumpers and ontributed greatly to his success, for only 18 those recorded in favour of his votes excep r. Barling received 42 plumpers and most Mr. Golding-B obably recorded by provincial Fellows. of these w on seems to be very prevalent amongst the The curio "plumping" more than one vote can be given voters th but it is not so; to plump for a candidate to a ca ly one vote. In one way it is fortunate that gives otherwise the work of the scrutineers, which is it is ans a sinecure at present, would be greatly in- by We give below fuller particulars of the election ere contained in THE LANCET of July 9th:—

	Votes.	Plumpers.
Mr. Barling	400	 42
Mr. Bowlby	327	 8
Mr. Eve	313	 53
Mr. Golding-Bird	265	 25
Mr. Bland-Sutton	251	 32
Mr. Bruce Clarke	212	 8
Mr. Harrison Cripps	170	 7

819 votes were received, of which 16 were personal votes

and 803 came by post, but one vote was invalid and five were received too late The following numbers of votes recorded for the last ten years—i e, since voting papers have been sent to all Fellows—may prove of interest 1895, 681, 1896 619, 1897 655, 1898 677, 1899, 493, 1900, 713, 1901 768, 1902 743, 1903 665, and 1904, 819 In the evening of the election day a dinner of the Fellows was held in the College building The Fellows' dinner was years ago a highly appreciated institution but it was never before held in the College itself More than 100 Fellows were present on this occasion and a very pleasant evening was spent The recent additions to the museum were on view and also many of the more remarkable specimens from the museum were displayed Some of the more valuable of the treasures of the College were to be seen in the Common Room We hope that even if it be found impracticable to hold a Fellows dinner annually it may be possible to arrange for one in alternate years The day of *election of members of the Council is very convenient for* several reasons and if all the arrangements are as perfect on subsequent occasions as they were this year there can be no cause for complaint This year for the first time no meeting of Fellows was summoned for, as will be remembered the persistent abstention of Fellows from these meetings prevented the formation of a quorum

CURIOUS RESULT OF LAXITY IN DEATH CERTIFICATION

IN the Philippines recently four criminals are stated to have been executed by the process known as garrotting and to have been certified as dead by a native medical man by *an American judge and by the other lay officials charged* with that duty Afterwards while the supposed dead bodies were lying in a church awaiting the funeral ceremony two of them showed signs of life and have since completely recovered to find that the record in their case has been closed and that they have no legal existence They are however, in spite of this retained in prison and it is suggested that if let loose they might commit further crimes although should they do so aggrieved persons killing them could not be punished for taking lives already officially extinct Their sentence has been changed to one of incarceration for life but the legality of this they dispute presumably on the ground *that the punishment ordered* in the first instance has been carried into execution If the story is true it might be suggested that as a precaution for the future the duty of death certification should be intrusted to one competent to perform it The qualifications of the medical man described in the account before us as a "native doctor are not stated

SUNSHINE RECORDS

IT is interesting to consider which property of sunshine is more important to life that of the heat-giving rays *or that of the chemically active rays* Both are, *of course* essential and although a person may be shivering in sunlight he may still be enjoying the benefit of the actinic emanations They are the agencies whereby the great synthetic processes in plant life are begun and continued They keep the machinery of nature in motion *and in being, they build up* food both for man and beast and if the chemical energies of sunlight were to cease life would flicker out Our knowledge of the chemical action of sunlight is, however, by *no means* complete In some way or other the advent of sunlight *increases* the *feeling of well* being of the individual possibly by promoting the oxidation processes of the internal economy The circulation is improved and the condition of the blood is favourably affected by its oxygen carrier being stimulated into activity Vitality, in a word, is increased and the exhilarating effect of the first burst of sunshine in the spring after a dull period in the winter is a common experience After all it is probable that "the brighter view of things" which individuals take under the influence of bright weather may have its origin in the chemical activities of the sun The health giving effects of sunshine may therefore be ascribed to the actinic rays rather than to the luminous rays of the sun The official records of sunshine in this country refer to the duration and not to the intensity, of the light In other words these returns record negatively the obscuration of the sun by cloud On the other hand, the temperature is *recorded in terms of intensity and it seems to* us that similarly the intensity or chemical activity of sun light should be recorded, for duration can bear no direct relationship to intensity. The sun might shine all day with a feeble intensity owing to meteorological conditions, haze *or fog and* conversely sunshine might only favour us *for an* hour and in that comparatively short time exhibit an intensity or degree of chemical activity equal to a day s duration The sunshine in mountainous places as in Switzerland is much more active chemically, as a rule, than the sunshine in the United Kingdom although in the latter place the duration might even exceed that of the former Amateur photographers experience this readily enough for they find that the exposure required for the sensitised plates on a bright day in Switzerland is infinitely less than that required under similar conditions in England In the former case the transparency of the air is greater and the actinic rays of the sun are not cut off as they are in this country Duration therefore is not necessarily a synonym for intensity and thus the value of comparative records of duration for different places may be discounted when any record of intensity is omitted No one would think of recording rainfall by its duration The actual amount of water falling would depend upon whether the shower was heavy or light or a steady drizzle The rainfall is therefore measured by the weight falling on a given area and it seems to us that the meteorological records should include not only the duration of sunshine but also its intensity as measured by its chemical effects If the *benefit derived from sunshine is due to its chemical energies* careful records should be kept of them especially at our health stations

NERVES OF THE SCLERA

THE nerves of the sclera have been investigated by the Russian physician Dr A Agagabow and the results which he has obtained are contained in the March number of the *Archiv fur Mikroskopische Anatomie* He finds that the best method to display them is the injection *in vivo* of methyl blue solution containing from 1 to 3 per cent with subsequent removal of the eye from the body, evisceration of its contents and careful section By these means the nerve endings can be followed to their finest ramifications and Dr Agagabow has been able to distinguish sensory, trophic and vaso motor nerves the last characterised by ganglion cells The sensory nerves are to be found in all parts of the sclerotic they are immediately recognised by being medullated though some lose their medullated sheath near *their termination* These fibres are varicose and exceedingly delicate and end in a nodule slightly larger than the varicosities In some instances a terminal brush like arrangement of varicose fibres is observable Where the nerve trunks cross vessels they may be sometimes seen to be *flattened out* and appear to be as much as two and a half times thicker than before or after crossing This peculiarity, which may be observed in other parts of the body, has not received the attention that it deserves from histologists

Dr. Agagabow gives illustrations showing the mode of termination of the sensory nerves. These are drawn with much delicacy. The vaso-motor nerves taken from the choroid are also shown which exhibit the disposition of the ganglion cells both singly and in groups. He states finally that in many sections of the sclera taken from white cats and rabbits finely granular nerve fibres may be met with which proceed from medullated nerve trunks and which form intercommunicating networks round endothelial cells.

PUBLIC-HOUSES AND THE SPREAD OF TUBERCULOSIS.

THAT the public-house is a fruitful source of infection by the tubercle bacillus is well known and the returns of the English Registrar-General show that public-house servants are specially prone to be affected by pulmonary tuberculosis. This is not to be wondered at when we consider that the floor of the lower class of public-house is covered with sawdust which in great measure is impregnated with sputum. This dust dries and is constantly being stirred up by the feet of drinkers. Not only are barmen and barmaids and the customers of the house thus exposed to infection but the unhappy children who are brought into the house by their mothers are likewise in danger. The public-house is the poor woman's club where she can discuss with her neighbours social and domestic incidents; the children cannot be left at home and so they sit on the public-house floor during their mothers' gossip-time. Only the other day passing a large public-house in one of the main thoroughfares of St. Luke's we noticed through the open door of a public bar several slatternly women drinking at the counter, while crawling on the floor of the bar and rubbing their hands in the saw-dust with which it was strewn were two babies of from 18 to 24 months old. That this is not an uncommon occurrence those who have occasion to visit poor and squalid neighbourhoods well know and in the light of such facts is it to be wondered that the race is said to be degenerating or that medical science should have such a hard up-hill fight with disease? Granting that these children, probably the offspring of degenerate beings, become infected with the bacillus of tubercle the environment in which they live will necessarily be a potent factor in the development of pulmonary tuberculosis and not only will they themselves suffer but they will also involve the public in great expense for their subsequent treatment and keep. Recently a law has been passed to prevent children under a certain age from obtaining intoxicants and there is legislation for the prevention of cruelty to children but as yet there is no law to prevent ignorant mothers from leaving their offspring to play on the disease-laden floor of a public-house. In another column we refer to the efforts being made to inculcate the precepts of hygiene at an early age, and many publicans, notably those in the borough of Woolwich, post up notices requesting their customers not to spit. But until spitting on the floor of a tavern is made a penal offence as it is at present to spit in a tramcar, there is but little hope of amelioration.

ON PUBLIC HEALTH AND SOME OTHER MATTERS.

THE Buddhist ascribes all evil to Avidyâ or ignorance, and whether the arguments by which he arrives at this conclusion be valid or not there can be no doubt that a large amount of bodily sickness, with its attendant pain and suffering, is due to this cause. To dispel the ignorance which creates disease is part of the work of the medical profession and in so doing it offers itself as a sacrifice to the cause which it serves. For does not its material existence depend upon the existence of the ills which it alleviates? Its reward is the satisfaction of duty well done, and more and more as our science continues in its progress is it seen that the work of medicine is becoming preventive. Our best energies are devoted to the forestalling of disease, instead of waiting, as in days gone by we were compelled to wait, until a manifested disease called for our therapeutics. In recent years, as thought and study have been devoted to the various aspects of public health, it has become obvious that endeavours to educate the masses of the people in those matters on which the general health depends offer the best chance of securing effective protection of the community. Medical men have consequently welcomed the aid of various institutions and societies which by collecting statistics, delivering lectures, and other methods have helped to awaken the members of the public to their responsibilities with regard to the care of family, community, and national health. Singularly little assistance in this direction has been received from the public press, the most powerful educative machine that we possess in other directions. So far from helping the cause of health, in too many cases the public press serves as a medium for puffing the quack. And even where the self-respect of editors and proprietors prevents this we are very generally treated to a curious exhibition of ignorance upon all medical topics. On the slightest hint of a new medical discovery inaccurate and highly coloured articles are written, holding out hopes to poor sufferers from diseases incurable—in the present state of our knowledge. If the press would become the vehicle of the dissemination of scientific knowledge instead of the medium by which the quack robs the public we should all have reason to rejoice. In the household ignorance of sanitary laws is often the cause of much disease otherwise preventable and in the case of infectious diseases the evil may be widespread. The want of knowledge of the most simple hygienic rules regarding food, ventilation, and cleanliness by the public as a body is astonishing. We are pleased therefore to see that a new movement is about to be initiated by the committee of management of the Hospital Saturday Fund, which has under its consideration a scheme for the establishment of a health department. It is proposed to form classes for the instruction of women in the elements of domestic hygiene, the lecturers to be medical men. The Hospital Saturday Fund is in touch with working men throughout London and the scheme if properly carried out ought, in the near future, to have an important influence on the health of the community generally.

INSANITY AND THE HEREDITARY NEUROSES ALLIED TO IT REGARDED FROM THE STANDPOINT OF VARIATION.

EVER since Morel of Belgium (1858) published his classical treatise on degeneration in human races the attention of alienists and neurologists has been drawn to the study of insanity as a problem of what the biologists call *variation*. In the *Edinburgh Medical Journal*, for May and June Dr. John Macpherson, Commissioner of Lunacy for Scotland, draws attention to the anatomical "stigmata" or physical signs of abnormal development present in the insane, and especially in the idiot, the imbecile, and the feeble-minded. The absence of certain mental faculties is, says Dr. Macpherson, "wholly or in part correlated with the development of the physical organisation, especially that of the central nervous system, and it is rare to meet with imperfect congenital structure of the nervous system in the absence of bodily imperfections." The more grave the incidence of the mental defect the more numerous and pronounced are the physical malformations. Thus, as we pass up the scale from monsters to idiots, imbeciles, and the higher classes of the latter we find a gradual diminution of physical stigmata of degeneration until they disappear altogether as we emerge upon the normal platform of the race. The mental defects which are correlated to these physical stigmata are manifested as epilepsy, hysteria, chorea, tics, and obsessions. An analysis of the causes acting on the germ cell or embryo so as to give rise to the defects or anomalies of idiocy, imbecility, and weakmindedness leads Dr. Macpherson to the conclusion that the vast majority (90 per cent.) of instances are due to modifications of the germ cell or the early embryo; in short, modifications of the germ plasma, so that the offspring born are in turn liable to transmit the defect or diathesis to their descendants. 10 per cent. of the cases are secondary to extraneous causes affecting the fœtus or newly born infant, such as difficult parturition and asphyxia, cerebral hæmorrhage, sensory defects from porencephaly and softening, and similar gross lesions. Dwarfism, says Dr. Macpherson, is often marked by physical (rachitic) deformity combined with a feeble intelligence, a point to which attention was called in THE LANCET[1] in an annotation on the relation of rickets to mental deficiency. Dwarfs are met with in every race and in most orders of plants and animals but, adds Dr. Macpherson, being pathological they are sterile and cannot procreate offspring. Absence of one or more fingers is correlated with acephalus, cynocephalus, or other grave malformation. "It is rare to see a diminution of fingers," says Geoffrey St. Hilaire, "in a non-monstrous individual." Polydactylism is, on the other hand, consistent with normal bodily and mental development and when it occurs in parents it is transmitted to the descendants with remarkable persistency. Dr. Macpherson quotes a classical case of the transmission of this defect for ten generations in a family, the transmission being effected by the female members only. Albinism, a condition of absence of the normal pigments of the skin, hair, and iris, is also "strongly inherited" (Lucas and Darwin), the formation of pigment being arrested early in fœtal life. A curious correlation of albinism with deafness is found in cats since albino cats with blue eyes (Darwin) are also born deaf. Dr. Felkin of Uganda states that idiocy is of frequent occurrence in albino children born of the natives. Germ cells or incipient embryos which are highly damaged or defective usually do not grow to full term but abort at the end of the first month of intra-uterine life, hence the relative fewness of full-born monstrosities. "But for this fact of abortion," adds Dr. Macpherson, "the relative number of human monsters [born at full term] would be infinitely greater than it is." Among the specific neuroses allied to insanity and which, like the latter, are transmissible by heredity are enumerated the following: epilepsy (which is ubiquitous in the human races), hysteria major (which is equally widespread), catalepsy, the phrensies occurring in spiritualistic "mediums" and "oracles," and dipsomania (a strongly marked craving for artificial mental states produced by alcohol and drugs, strongly hereditary, and usually commencing at the adolescent period of life). Many other bonds of similarity exist between dipsomaniacs and the insane, showing, concludes Dr. Macpherson, that the victims of dipsomania are variations from the normal type.

CONTAGIOUS ABORTION IN CATTLE.

THE contagious, specific, or infectious abortion of cattle has long been a source of great monetary loss to all breeders of such animals. At the request of the Board of Agriculture Professor Cave, F.R.C.V.S., has carried out a series of observations on its prevention the results of which have been issued in a leaflet published by the Board. This form of abortion, which may be defined as an infectious catarrh of the womb due to a specific organism and readily transmitted from one animal to another, produces in some herds a very large number of abortions every year, and once it has been introduced is very difficult to stamp out. The percentage of cows that may abort in a herd affected by this disease often amounts to as much as 50 per cent. of the whole number. If we estimate the monetary loss at, say, £7 10s. in each case it is clear that the total loss experienced by dairy farmers throughout the country is very large. The treatment adopted by Professor Cave consisted either in the internal administration of carbolic acid and the local application of various antiseptic lotions or in the use of local antiseptic applications alone. The internal administration of carbolic acid alone was also tried but with little result. When, however, reliance was placed on the external use of antiseptics the results obtained were most encouraging. In the case of a herd in which the loss from infectious abortion had amounted to from 25 to 50 per cent. of the calves during the last 18 years the following treatment was adopted. The anus, vulva, under surface of the tail, thighs, and udder were sprayed with a watery solution of izal (1 in 80) three times weekly. The cowsheds were cleansed by the use of lime-wash and common carbolic acid, while the under surface of the roofs was sprayed with izal solution (1 in 200). The lime-washing and the spraying of the roofs were done every three months and the floors and drains were washed with a solution of izal of the same strength three times a week. All cows which had aborted were carefully isolated, fattened, and sold. The experiment was carried out for a period of three years. During the first year four cases of abortion occurred and two cases of premature delivery. Two of the cases of abortion were in heifers which had not received any treatment at all. The outbreak, which was one of many years' duration, ceased entirely after eight months of treatment. In another case this method of local antiseptic treatment was combined with the internal administration of carbolic acid. Here almost equally good results were obtained, no doubt mainly due to the local treatment and not to the administration of the carbolic acid. Professor Cave's results clearly show that contagious abortion can be prevented by the adoption of appropriate local antiseptic treatment for the cows and if necessary for the bull and that it should be combined with the strict isolation of all cows which have aborted and their subsequent sale and the destruction by burning of the fœtuses, placentæ, and membranes. The experiments are of great interest to medical men as showing how successfully antiseptic treatment can be employed in veterinary obstetric medicine and are of the utmost importance to breeders of cattle who now know what precautions they should take when their herds become affected with this dangerous but preventable disease.

TREATMENT BY INTRASPINAL INJECTION OF DRUGS.

AT the meeting of the Académie de Médecine, Paris, held on June 14th Dr. Jules Glover read a paper of considerable practical interest on the intraspinal injection of various alkaloids as a means of treatment. He finds in severe conditions of renal inadequacy in the course of cases of heart disease with cardiac failure, in cases of severe diarrhœa with collapse, and in high-tension or low-tension conditions of the circulation that even after ordinary methods of treatment have failed the injection under antiseptic precautions of strong solutions of certain alkaloids gives satisfactory results. The alkaloids which have so far been tried are caffeine, pilocarpine, and atropine—that is, drugs with a powerful direct and general action on the central nervous system and the functions which it controls. In order to avoid too rapid spread of the drug to the higher centres it is important to give it in a solution isotonic with the cerebro-spinal fluid, and for this purpose it is necessary to carry out cryoscopic experiments to determine the osmotic pressure of the solutions. In experiments on rabbits it was found that solutions of these three alkaloids in small doses produced the usual effects of these drugs with a much greater rapidity and intensity and with more permanent results than when given by any other channel. In a case of cardiac failure and renal incompetence with general œdema, ascites, and uræmic symptoms in man, the intra-arachnoid injection of a solution of 0·25 centigramme of caffeine per cubic centimetre (*0·25 centi-cube*), followed on two occasions at intervals of three days by injections of 0·40 centi-cube, re-established the renal functions, raised the blood pressure, and facilitated the action of ordinary methods of treatment which had previously failed. It is needless to insist on the importance of rigid aseptic precautions in applying this method of treatment. The solutions should be from one-third to one-half or even as much as a cubic centimetre in volume, they should be neutral or slightly alkaline in reaction, and must be freshly prepared. Acid solutions of alkaloids, particularly quinine solutions, produce in animals immediate death. These observations by Dr. Glover, admittedly incomplete though they are, are yet of great interest as indicating a method of introducing drugs as a last resort in cases where their administration by ordinary channels is ineffective or impracticable. Lumbar puncture is now well known to be a comparatively simple process and often of great value as a diagnostic or therapeutic means. The administration of drugs in this manner should therefore also be a matter of very little difficulty. Although the method is not entirely new, since the intraspinal injection of cocaine has been extensively tried abroad, its application to the treatment of general conditions is an advance. Apparently, from Dr. Glover's account, if the precautions which he advises are adopted the method is harmless; at the same time it is obvious that if acid solutions like those of quinine have serious results the utmost care will have to be exercised in the use of this method.

---

[1] THE LANCET, Jan. 10th, 1903, p. 117.

THE SCOTTISH POOR-LAW MEDICAL SERVICE.

IN THE LANCET of Jan. 9th we referred to the case of Dr. J. F. D. Macara, the Poor-law medical officer of Durness in Sutherlandshire. Dr. Macara had been threatened with dismissal by his parish council in the high-handed manner which is legal in Scotland. Dr. Macara, however, found means of commencing an action against the council and an injunction was obtained restraining the council from appointing anyone in Dr. Macara's stead. The parties eventually came to an agreement on the subjoined terms :—

1. The council to rescind their minutes of Nov. 6th and 20th, 1903; to withdraw the threatened dismissal of Dr. Macara and to reinstate him in his office. Although the council cannot legally enter into any binding contract in regard to the future duration of Dr. Macara's tenure of office it is honourably understood between all parties concerned that the [illegible] re Dr. Macara's dismissal in consequence [illegible] transpired, and that the settlement now [illegible] to end all ill-feeling between the parties. [illegible] all charges made against Dr. Macara, and [illegible] "breach of duty" against him in respect of the dictated certificate regarding Barbara Macpherson, and to acknowledge Dr. Macara's *bona fides* in all his actings throughout the present dispute.

3. Dr. Macara to render quarterly an account for medicines and medic[illegible] supplied by him to paupers and the same [illegible] council.

4. The [illegible] communicated to the *Scotsman* and *Glasgow Herald* newspapers and the local press, and to THE LANCET and *British Medical Journal*.

5. The council to pay the account of expenses incurred to Messrs. Inglis Orr and Bruce, W.S., in connexion with these actions as between agent and client, or in the option of the said Inglis Orr and Bruce the sum of £100 in full of all their said expenses.

6. The foregoing terms of settlement to be minuted verbatim in the minute-book of the council and to be given legal effect to by formal resolutions of the council. The minute-book containing said minutes and resolutions engrossed therein to be exhibited to Dr. Macara, who may make copies or extracts therefrom.

7. On the foregoing terms being implemented both parties will consent to the action of suspension and interdict and the action of reduction being dismissed by joint minute, and Dr. Macara will consent to waive his claim to damages against the council in respect of his attempted dismissal.

We congratulate Dr. Macara upon the result of his action, for to him, perhaps, more than to anyone else is due the fact that the grievances of the Scottish Poor-law medical service have become so widely known. But there can be no safety for Scottish Poor-law medical officers until their dismissal has to be approved by the Local Government Board in the same manner in which it now has to be approved in England and in Ireland.

TRAUMATIC RUPTURE OF INTESTINE.

THE *American Journal of the Medical Sciences* for June contains an important paper by Dr. E. J. Senn on Traumatic Intestinal Rupture with special reference to Indirect Applied Force. The subject merits greater attention than it has received. The degree of external injury of the abdomen is no criterion of the gravity of the internal injury. A slight abdominal contusion may be followed by great damage of the underlying viscera, while a crush sufficient to fracture neighbouring bones may leave the viscera intact. Intestinal injuries may be due to direct or indirect force. In the former the force is applied through the abdominal wall against the exposed intestine; in the latter the force is applied to the buttocks or the lumbar region. The possibility of rupture of the intestine being produced in the latter manner is liable to be overlooked. After a careful search Dr. Senn could find recorded only two well-authenticated cases. Dr. J. F. Bottomly has reported a case in which a patient was struck in the back below the left scapula by an approaching wagon and on operation perforation of the first portion of the jejunum was found.[1] Dr. Westbrook has described a case in which a man was struck in the lumbar region by a wagon-pole and the necropsy revealed a rupture at the junction of the duodenum and jejunum sufficient to admit two fingers.[2] Dr. Senn now reports the following case which shows the possibility of slight force applied to the buttocks producing laceration of intestine. On July 17th, 1903, at 6 P.M. a married woman, aged 26 years, while hurrying slipped and fell on the right buttock. She had just taken a hearty supper. No serious symptoms were noticed and she retired to bed as usual. At midnight she awoke with severe abdominal pains and vomited. On the following day she was seen by her medical attendant who prescribed opiates and turpentine stupes. The pains increased and she rapidly grew worse. On the 19th Dr. Senn saw her in consultation. She had an anxious appearance and complained bitterly of abdominal pains. The temperature was 104·3° F. and the pulse was 140. There were diffuse abdominal tenderness and marked tympanitis, especially in the region of the appendix. But for the history of injury appendicitis would have been diagnosed instead of perforative peritonitis. On opening the abdomen cloudy fluid escaped but no gas. On separating filmy adhesions of the great omentum there was a gush of fluid loaded with flakes of fibrin. The small intestine was greatly distended, of a bluish-black colour, and covered with lymph. After long exploration a sudden escape of gas was noticed deep down in the pelvis. Fæces were found in the peritoneal cavity and a small perforation of the size of the little finger nail in the jejunum. The abdominal cavity was cleansed by dry sponging, the perforation was sutured to the abdominal wound, and drainage was provided. Enterostomy was performed in consequence of the collapsed state of the patient and the paralytic state of the intestine. The patient recovered with a fistula which required a second operation. The fact that the fall was not severe was borne out by the absence of soreness or bruising of the buttock. The state of the abdominal muscles at the time of an injury plays an important part in the result. A blow on a rigid abdomen loses considerable force, while a blow on a relaxed one is transmitted with full force to the underlying intestines. Sometimes the bowel is not ruptured but only contused. Cases are recorded in which after an injury the patient did well for days and even weeks and then symptoms of perforative peritonitis arose and the necropsy showed a perforation. Mr. Thomas Bryant has recorded two cases in which such perforation took place on the fifth and nineteenth days after the injury respectively.[3] The contusion no doubt led to necrosis of the intestine. Severe abdominal injuries first produce shock. The more serious symptoms soon pass away unless there is injury of the abdominal viscera or internal hæmorrhage. If there is intestinal rupture with fæcal extravasation the symptoms of shock merge into those of general perforative peritonitis. In cases of contusion or incomplete rupture of the intestine after the symptoms of shock subside there is some pyrexia in consequence of the local peritonitis but there is not much change in the pulse. Constipation or diarrhœa may be present and possibly blood-stained stools. There are slight abdominal pain and tenderness. Such cases usually follow a favourable course. On the other hand, in cases of immediate extravasation of the intestinal contents there is at once excruciating pain, the face is pale, the pupils are dilated, the respiration is superficial, the pulse is small, and the temperature is subnormal. Vomiting soon follows. The abdomen is first rigid; later it is distended. The prognosis of rupture of the intestine depends on early diagnosis and operation. Thus according to Siegel's statistics the mortality of cases operated on in the first four hours was 15·2 per cent.; within five to eight hours, 44·4 per cent.; within nine to 12 hours, 63 per cent.; and later, 70 per cent. In all cases of abdominal contusion the rule should be to give a guarded prognosis, to keep the patient under careful observation, and upon the least suspicion of rupture to operate.

VACATION COURSES IN BACTERIOLOGY AND PATHOLOGY AT KING'S COLLEGE.

A COURSE in practical and clinical bacteriology will be held daily at King's College, London, from 10.30 A.M. to 1 P.M., *commencing on Wednesday, August 3rd, and ending* on Saturday, August 13th. The course will consist of lectures, demonstrations, and practical work; in the latter the members of the class will make for themselves *permanent preparations of the chief pathogenic micro*-organisms and will carry out the principal manipulations employed in bacteriological investigations. The fee will be £3 3*s*., inclusive of materials. Names should be sent in as soon as possible to the secretary or to Professor R. T. Hewlett. A course in clinical pathology will also be held on six afternoons from August 3rd to 13th from 2 to 4.30. The course will consist of demonstrations and practical work; the inclusive fee will be £2 2*s*. If both courses are taken the inclusive fee will be £4 4*s*.

OPERATION FOR PERFORATED GASTRIC ULCER.

THE mortality after operation for perforation of a gastric ulcer appears to be diminishing. Mikulicz was the first to operate for this condition in 1880 but it was not till 12 years later, in 1892, that we have any record of a successful case, when Kriege sutured a perforation and the patient recovered. At first the mortality of recorded cases was very high and in all probability the mortality of all cases treated by operation was still higher, for unsuccessful cases are never so readily recorded as the successful. Several factors have concurred in lowering the death-rate. Experience has taught us the best methods of operating and practice has enabled us to operate more quickly, but probably the chief factor in lessening the mortality is the fact that cases are operated on at an earlier period after perforation and as the length of the interval between the perforation and operation is the chief element in the prognosis we must look upon any reduction of this interval as a potent agent in reducing the death-rate. Practitioners are more ready in invoking the aid of the surgeon now that they are acquainted with the value of early surgical treatment and the public more readily submit to operation. It is not improbable that the mortality in hospital practice after operation for gastric perforation is less than in private practice, for in hospitals there is much less delay in preparing for an operation than is generally necessary when an operation has to be performed in a private house. In the present issue of THE LANCET are recorded the notes of nine consecutive cases of operation for perforated gastric ulcer at St. George's Hospital. Eight of these patients recovered and the only death occurred in a patient in whom perforation had probably taken place 48 hours previously and who had had to travel about 100 miles before operation. These results are excellent and reflect credit on the surgeons who performed the operations.

OPTICIANS AND SPECTACLE PRESCRIBING.

THE following report on Sight-testing by Spectacle Makers has been issued by the Ophthalmological Society over the signature of the President of the society, Mr. John Tweedy, F.R.C.S. Eng.:—

> [illegible] Kingdom, having had its
> [illegible] pful Company of Spectacle
> [illegible] ht-testing in the examina-
> [illegible] of efficiency therein, wishes
> [illegible] s which
> [illegible] work, it
> [illegible] public to
> [illegible]
> [illegible] s of the
> [illegible] s would
> [illegible] e life of
> [illegible] an only
> [illegible] ld only
> [illegible] minate
> [illegible] the eye
> [illegible] ble and dangerous
> [illegible] any organ of the
> [illegible] with its anatomy
> [illegible] ns to which it is
> liable.

This, of course, is the exact position which THE LANCET has always taken up. That the widespread need for reading spectacles in middle age can to a great extent be met by treatment based upon optical rules of thumb does not alter the fact that the eye is a living organ as well as an optical instrument. As a living organ it is subject to malformations and diseases which complicate, and are complicated by, its optical defects. It is impossible for anyone to deal with the latter who is not able also to appreciate the existence and influence of the former.

A TELEGRAM from Lord Milner, received at the Colonial Office on July 9th, states that for the week ending July 9th the plague return for the Transvaal was as follows: New cases 2—namely, 1 white and 1 coloured person—making the present total of suspected and proved cases 149—namely, 28 white and 121 coloured persons. There were no deaths during the week.—As regards Hong-Kong, a telegram from the Acting Governor, received at the Colonial Office on July 12th, states that for the week ending July 9th there were 24 cases of plague and 21 deaths from the disease.

DEFECTIVE SIGHT IN SCHOOL CHILDREN.—At the meeting of the Plymouth education committee held on July 4th it was decided to engage the services of an ophthalmic surgeon at a salary of £40 per annum for the examination of cases of defective sight in the elementary schools of the borough.

[3] THE LANCET, Dec. 7th, 1895, p. 1419.

THE IMPERIAL CANCER RESEARCH FUND.

THE third meeting of the general committee of the Cancer Research Fund was held at Marlborough House on July 8th. H.R.H. the Prince of Wales, the President, occupied the chair and amongst those present were Adeline Duchess of Bedford, Lord Strathcona, Sir William Broadbent, Sir William Church (President of the Royal College of Physicians of London), Sir Alfred Cooper, Sir Henry Howse, Sir Douglas Powell, Mr. Julius Wernher, Mr. John Tweedy (President of the Royal College of Surgeons of England), Mr. Henry T. Butlin, Mr. John Langton, Mr. R. Littlejohn, Professor J. McFadyean, Dr. P. H. Pye-Smith, Mr. S. Neumann, Professor G. Sims Woodhead, Mr. Henry Morris (honorary treasurer), Dr. E. F. Bashford (general superintendent and director of the Central Laboratory), and Mr. F. G. Hallett (secretary).

The SECRETARY having read the minutes of the last meeting, which were duly confirmed,

The PRINCE of WALES called upon Sir William Church to move the adoption of the report, an abstract of which follows.

ABSTRACT OF THE SECOND ANNUAL REPORT OF THE CANCER RESEARCH FUND.

Report of the Secretary.

The executive committee has met every month in this the second year of the existence of the Fund, except in August and September, and at each meeting the general superintendent, Dr. E. F. Bashford, submitted a report of the work in hand for the consideration of the committee. The work, which was always fully explained and discussed, is set forth in Dr. Bashford's report and shows the scope of the organisation for carrying out the original intention of the scheme, for extending the investigation to all parts of the world, for encouraging others by means of grants, for pursuing some definite lines of inquiry, and for guiding public opinion on matters relating to the subject, as well as the investigation of the constantly reported cancer "cures." At the meeting in July the appointment of an actuary was authorised for statistical purposes and the laboratory staff was increased to meet the demands of the research. The negotiations for the acquisition of a farm where animals suffering from cancer may be kept under observation for therapeutical and other purposes were brought to a successful conclusion in November and at the December meeting the lease was agreed to and possession was obtained. At this meeting it was also decided that any scientific publications relating to the work of the Cancer Research Fund shall be made officially in the name of the executive committee. The conditions under which grants from the Research Fund may be made to those who are working at problems bearing on cancer were determined at the meeting in March and are as follows: 1. Grants shall only be made to individual workers for definite work, the nature of which shall be stated at the time of application, and which shall receive the approval of the executive committee. 2. The results of work done by the aid of such grants shall be submitted to the executive committee. 3. The publication of such results, if sanctioned by the executive committee, shall be made in the scientific reports of the Cancer Research Fund or in such other manner as the executive committee may approve. 4. Any material supplied by the director or executive committee for investigation shall be considered the property of the Fund and any results of research in connexion therewith shall be acknowledged as having been done in connexion with the Cancer Research Fund. The first grant of £200 was made on the recommendation of the pathological subcommittee to Professor J. Brentland Farmer, F.R.S., of the Royal College of Science to enable him to continue his researches on the cytology of malignant and other growths. Dr. W. Cramer, Ph.D., was in April appointed assistant to Dr. Bashford to carry out special bio-chemical investigations.

Report of the General Superintendent.

Except those portions of the investigation which it has been necessary to conduct at the farm, the work has been carried out in the office and central laboratories placed at the disposal of the Cancer Research Fund by the Royal Colleges of Physicians and Surgeons. This accommodation has been fully occupied and has proved eminently suitable and convenient. The possession of a farm for accommodating the larger kinds of animals has been a necessity. Up to February this accommodation continued to be generously provided by a member of the executive committee. Since that date the farm secured by the executive committee has been adapted to the purposes of the investigations and a number of animals has been under constant observation there. The comparative biological and experimental line of inquiry has been proved to have the value which was predicted for it when starting the work of the Cancer Research Fund and to which attention was drawn a year ago. Facts have been thereby brought out which have a fundamental bearing on several of the crucial problems of cancer and give definite indication of the line for future inquiries. The discovery of a fertilisation process in transplanted tumours explains much that has hitherto been absolutely obscure. The investigations which have been made during the past year may be conveniently described under separate headings.

I. *Experimental work on the nature and processes of growth of cancer.*—[The work referred to under this heading has already appeared in THE LANCET.[1]]

II. *Experimental investigations bearing upon the diagnosis and treatment of cancer.*—An essential preliminary to the problems involved in attempting to modify the growth of cancerous tissue must be the possibility of producing at will by transplantation the disease in animals in order to provide an adequate supply of tumours. This has been accomplished in certain experiments which have been made and is being further tried in experiments in progress. By means of the experimental observations thus rendered possible, various procedures which may legitimately be conceived to modify the powers of growth of transplanted tumours, or to yield specific evidence of their presence, have been studied. Thus a serum has been obtained capable of acting upon the tumour cells in the test-tube. Attempts, however, to produce the same effects in actively growing tumours in living animals have yielded negative results. The artificial transplantation of malignant tumours has been utilised to seek for specific evidence of their presence in an otherwise normal animal. The only [illegible] transplantation is the de [illegible] oculation, unaccompanied by any constitutional disturbance of a specific nature. Subsequent microscopical examination is necessary to determine the nature of the lump. In the number of animals which have been studied while suffering from primary new growths no specific symptom of the presence of the latter has been observed, and the conclusion of necessity is drawn that cancer *quâ* cancer in man and animals is still without a specific symptomatology. This conclusion loses its apparent surprising features when the results of the examination of transplanted tumours and of primary tumours as regards their microscopical characters are borne in mind. As already stated, the cells introduced by transplantation themselves grow and produce the new tumours, and the latter present characters identical with those of the tissue in which the primary tumour arose and never cell-masses of heterogeneous type. Artificially transplanted tumours afford the most favourable circumstances for testing the claims made on behalf of various reputed empirical therapeutic methods. Of these the number brought to the notice of the Cancer Research Fund is very great. It has been necessary to examine in detail the action of radium bromide. Tumours of the mouse transplanted subcutaneously have been subjected to the action of radium bromide and in some cases the rate of growth has been diminished; in other cases it has ceased altogether and the tumour has practically disappeared. In other cases, again, no action has yet been observed. It has been necessary to determine in how far the susceptibilities to radium rays of the tumours and other tissues vary and for this purpose control experiments are being carried out. They are not yet concluded but there is no doubt that the action of radium is not limited to cells of the malignant tumours. Subcutaneous transplanted tumours of small size are peculiarly accessible to, and favourable for, the manifestation of the action of radium but afford no ground for predicting the curative effect of radium upon deep-seated primary tumours.

III. *Statistical* [illegible] method of tabulating malignant new gr[illegible] case of the hospital statistics given in the first annual report has been adopted by

---

[1] THE LANCET, Feb. 13th. 1904, p. 413, et seq.

Dr J F W Latham in recording the mortality from cancer in England in the Sixty fourth Annual Report of the Registrar General for 1901 At the request of the statistical sub committee Dr Latham a year ago reported what steps could be taken to secure a fuller utilisation of the data on which the returns of the Registrar General are based At the time of drawing up the last annual report a special grant had been made by the executive committee for the employment of certain clerks in the General Register Office to abstract the facts from the registers setting forth particulars of the type of disease and organs affected with the object of ascertaining the relative incidence of fatal cancer on the more important occupations Dr Tatham has found it needful, however, to have this investigation made for the forthcoming census reports on a larger scale than was originally intended The investigation is still proceeding, and in the circumstances it has not been necessary for the Cancer Research Fund to defray the expenses

Hospital statistics —It has been possible to devise a plan whereby many of the London hospitals place at the disposal of the Cancer Research Fund succinct accounts of all the cases of cancer which have been subjected to microscopical examination The arrangements have been in working order for about nine months The practical result of the scheme is a card index recording all the important features of each case provided by the registrars of the different hospitals This admits of the ready analysis of the facts in various directions—e g , organ age, and sex incidence comparison of the clinical manifestations with the result of microscopical examination, influence of heredity, locality &c The total number of cards which have been received is 1913 The segregation of malignant new growths into those with characteristic manifestations and those without adopted in the first annual report has proved justifiable and instructive It has revealed the relatively frequent occurrence of conditions simulating malignant new growths and therefore explains many reputed cures of cancer

The ethnological distribution of cancer —It is too early to draw conclusions on the relative frequency of cancer in the various races of mankind from the facts which have accumulated on the incidence of cancer in various uncivilised native races of the empire It may be pointed out however that it is just where this evidence is most valuable that the various officials and private individuals who are engaged in searching for it meet with difficulties in their observations which only the most energetic efforts can overcome It is therefore interesting to know that specimens of cancer—carcinoma and sarcoma—have been obtained for the first time from certain native races inhabiting various tropical regions

The nature of the discrepancy in the recorded cancer death rate in Ireland and Great Britain —By persistent inquiry it has been possible to obtain from most of the hospitals and dispensaries in Ireland data regarding the total number of in patients and the total number of cases of cancer occurring among them The returns from general hospitals give a total of 110 646 in patients and of 3017 cases of cancer There is thus one case of cancer in every 36 patients The corre

the hospitals of the two countries In the course of the inquiry the fact has been ascertained that autopsies are performed with minimal frequency in Irish hospitals whereas in London hospitals they are responsible for adding largely

of the facts elicited on the diagnosis of cancer in London and Irish hospitals reveals the magnitude of the differences which may exist between the recorded frequency of cancer

an

an

ma

in Ireland The discrepancy between the recorded frequency of cancer in London and Irish hospitals can be explained solely by the heavy disadvantages under which the search for cancer is carried out in the latter The only conclusion possible is that among that proportion of the Irish population which does not have access to hospitals a still higher percentage of cases of cancer remains unrecorded, with the result that the relative frequency in hospital and the relative infrequency outside of hospitals together co cancer mortality throughout ability the more favourable ad if they existed in Ireland would quickly demonstrate there a cancer death rate proportionately higher than that of England in accordance with the higher age constitution of the Irish population

The bearing of the provisional results upon the reputed increase of cancer —The statistical and experimental investigations especially those relating to the transmissibility of cancer have a bearing upon the interpretations which others have put upon the increase in the recorded number of deaths from malignant new growths The results of the investigation into the difference in the recorded death rate from cancer in England as compared with Ireland has proved the absence in the latter country of various factors which are known to augment the number of deaths assigned to cancer in England , and the inference is justifiable that cancer is less frequently recorded in Ireland because the means for observing it are less adequate than in England Stated generally, the facts ascertained show a gradual diminution in the precision and completeness with which cancer is recorded among the inhabitants of England of Ireland, and of various outlying parts of the empire, till a minimum is reached in the case of the natives of certain tropical colonies A similar gradation is evident in the case of the domesticated and wild animals The extent to which cancer is recorded is inversely proportional to the difficulties which have to be overcome in obtaining information

Report of the Honorary Treasurer for the Year ending June 24th 1904

Twelve months ago the donations amounted to £49 686 9*s* 6*d* the interest and dividends derived therefrom gave £896 13*s* 6*d* and the total expenditure had been £997 2*s* 3*d* thus the working expenses had encroached upon the capital to the extent of £100 8*s* 9*d* During the past year donations have been added to the extent of £25 334 3*s* thus bringing up the total amount received to £75 020 12*s* 6*d* The interest on deposit account and dividends on invested stock have yielded during the year £1727 8*s* 5*d* whilst the total expenditure has reached the sum of £2987 10*s* 6*d* showing a still further encroachment upon capital of £1260 2*s* 1*d* It is impossible to refer to the donations received during the financial year now just concluded without particularising in terms of the deepest gratitude the munificence of Mr William Waldorf Astor who, in August last contributed the sum of £20,000

As the Cancer Research Fund has not had the advantage possessed by the Royal Commission on Tuberculosis—namely a complete farm placed at its disposal for the purpose of carrying on investigations for an indefinite time—its farm account will necessarily be an annual charge upon income The scientific staff already fully if not indeed, over worked cannot possibly be reduced but on the other hand in all probability will have to be increased as times goes on, whilst the acquisition of sufficient statistical material of a perfectly reliable character will demand a continuance for at

ce of the registering

Though only the very

gentlemen for each

the clinical patho-

cs of cancer—yet the

total sum is not likely to be less than £200 per annum

It ought to be mentioned that all the laboratory and the

ncer Research Fund has

College of Physicians of

eons of England free of

rent and indeed without charge of any kind for fuel, lighting and other incidental expenses whilst the executive committee—members of which attend the monthly meetings with great regularity—give their services gratuitously One of the members of the executive committee, who desires that

put the fund under a

rously providing farm

e investigations up to

February last when the animals were able to be received upon the farm now rented by the Cancer Research Fund

Every effort is made by the executive committee to keep down expenses as far as is consistent with efficiency and the wide scope of research but in spite of the strictest economy the annual expenditure in the immediate future cannot be less than £3000. It is therefore very disappointing that the capital sum required to yield an income equal to the expenditure is still far short of the necessary amount. From the outset the promoters of the Cancer Research Fund realised that £100,000 is the lowest sum which would be sufficient to defray expenses if the capital was to be left untouched. It is, and has from the first been, a great object in view not to expend any part of the principal, so that in the event of the nature and cause of cancer being discovered the fund should be available for the utilisation and application of this new knowledge in preventing and curing the disease; or that it should be reserved for the purpose of expending the income in conducting other researches of similar importance. It is a notable and significant fact that up to the present time only 328 individuals and ten City guilds have contributed to the fund. The excellence and large amount of work already accomplished by the scientific staff is most encouraging for the future and affords good reason why, before another annual report has to be written, at least the minimum sum needed for the complete and continuous prosecution of the research ought to be subscribed.

Sir William Church then moved the adoption of the report, commencing by regretting the absence of the Prime Minister to whom this duty had been allotted. With regard to the statistical investigations of the Cancer Research Fund, which do not seem to point to an actual increase in the number of deaths due to cancer, he expressed himself as exceedingly anxious that the position should not be misunderstood by those present at that meeting or by the public. Cancer, he said, may or may not be on the increase, but, he pointed out, we are not in a position to give a definite answer to that question, for this reason—that the statistics of cancer are not trustworthy for purposes of comparison—that is to say, we cannot compare the rate of deaths attributed to cancer now with the rate of deaths attributed to cancer 30, 20, or 10 years ago, and continued as follows with special reference to the statistics of cancer at the London hospitals. Of the malignant growths taking place in some accessible positions 91 per cent. have characteristic manifestations whereas of those which are inaccessible—that is to say, where the growths cannot be seen or readily detected—there are only 60½ per cent. which have characteristic manifestations. If you take the whole of those three groups together you find that of them 89 per cent.—really you may say 90 per cent.—present characteristic manifestations. In other words, of the growths in accessible or in what are termed intermediate positions 90 per cent. odd have characteristic manifestations and are recognised as cancer, and 8 per cent., or very nearly 9 per cent., have no characteristic manifestations and consequently may escape observation; and of those in inaccessible positions very nearly 39½ per cent. have no characteric manifestations and may escape observation. Now these are not cases such as those collected by the Registrar-General—cases of deaths attributable to cancer or cases in which cancer is supposed to exist but they are all cases in which the presence of the disease has been verified by microscopical examination. So that, to sum it up very briefly, if you take the whole of those figures you find that of the malignant growths which are under observation in the London hospitals there are 22 per cent. which are not recognised. Now that is very striking, and I think we may safely conclude, considering the difficulty of obtaining accuracy in these statistics in the London hospitals where the patients are under the observation of most competent persons not only of those who treat them but also of students who are daily looking out for symptoms, that the error is greater in the statistics of the general population of the country. Sir William Church concluded his remarks on the prevalence of cancer by expressing a wish that it should not go out authoritatively that the Cancer Research Fund had said that cancer had diminished, because it had been admitted that there are no data at present by which we can form an opinion as to whether the alleged increase is real or not. He then alluded in some detail to the excellent biological work done by Dr. Bashford and Dr. Murray in connexion with cancer, and reference to the publication of which in The Lancet has already been made, and concluded by summarising the present position with regard to treatment and by alluding to the need for more money. Sir William Church made quite clear to his audience that as yet no curative methods are recognised as superseding surgical interference, especially saying of radium "that it has an effect upon cancer cells is undoubted but this is an effect which it also has on normal tissues. It cannot be in any way regarded at present as having shown any indication that it is in any way curative of the disease. Cancer cells appear to undergo absorption and diminution under its influence but so do also the normal cells and tissues."

Sir Henry Howse, in seconding the motion for the adoption of the report, referred to the possibility which has been shown in the course of the last year of transplanting cancer in animals of a similar species and so carrying it on. It is not only the fact that the transmissibility of cancer has been proved, he said, but this fact opens up a great possibility in the future to investigations which would otherwise be extremely difficult.

The motion was carried unanimously.

Mr. W. Waldorf Astor, who recently gave £20,000 to the fund, having been elected a Vice-President and Mr. Watson Cheyne having been re-elected a member of the executive committee,

Lord Strathcona then moved a vote of thanks to H.R.H. the Prince of Wales for presiding over the meeting, and pointed out that the countenance and support given to the work by His Royal Highness would have the best effect in inducing people not only in England but in all parts of the world, in India and in our colonies, to give their attention to a very important matter.

Mr. Tweedy having briefly seconded the motion, it was *carried with acclamation.*

The Prince of Wales then said: My Lord and Gentlemen,—In expressing my gratitude for the hearty way in which this vote of [illegible] posed and seconded by my noble friend [illegible] Mr. Tweedy, and received by those who have kindly supported me here to-day, I wish to say what pleasure it gives me, as President of the Cancer Research Fund, to be present at this the third meeting of the general committee. The report which has been circulated among you, apart from its technical details, contains information which cannot fail to be of much importance to the public generally, while we who are met here to day have listened with interest to the excellent speech which has been made by Sir William Church in moving its approval and adoption. I know you will join with me in congratulating the executive committee, the general superintendent, treasurer, and secretary on the satisfactory results of their labours during the past year. Without presuming to tread upon the ground of so essentially a technical character as that of the report, I may say that the progress which it records is of good augury, for I gather that the facts which have been ascertained showing how cancer cells propagate themselves may be of immense importance in obtaining a true knowledge of the disease. The investigations of the Cancer Research Fund have brought to light in an unexpected degree how universal the disease is. We now realise that it exists in all parts of the globe, in man and in animals, wild as well as domesticated. It has been said that this terrible scourge is the result of civilisation, but the research has obtained reliable evidence of cases, amongst others, in tribes in the Hinterland of our African protectorates, far removed from any influence of civilisation. Recognising how world-wide the disease is, the Research Fund has wisely extended its inquiries to the farthest limits of the Empire, as shown by Dr. Bashford's report. Those endeavours have been fully seconded by the authorities in India, of our colonies, of our various protectorates, and by the willing support of the Ministers at the head of these respective departments at home. I also wish to express my satisfaction at the hearty coöperation between the workers of the Research Fund and our friends in America and in the principal European countries. We owe much to the colonies. One of the principal donations to the fund came from the representative in this country of Canada. The Government of Hong-Kong has placed an annual sum of £30 on the estimates as a contribution to the fund. New Zealand sent us some of the first and most valuable material on the occurrence of cancer in fish. Considering the far-reaching interest in the subject and that our organisation to be successful must be extended throughout the empire, it was felt that further advantage to its labours might be secured if an addition to its title could be sanctioned, and I am glad to have this opportunity of stating that the King has approved of the fund being known for the future as the "Imperial Cancer Research Fund." There will also be a further advantage in this designation, that the work of the Research Fund will

takings, most valual

from their nature are more local in their scope and limited in their resources But the continued progress of the investigation makes ever increasing demands upon the fund, and the treasurer s report points out that up to the present only 328 individuals have contributed to the fund I am sure no words are required to plead the cause of this great national work, so important to the whole race of mankind There are few of us, unfortunately who have not had brought home to us the terrors of this fatal, mysterious disease, and does it not behove us, in the interests of humanity and science, to assist, to the utmost of our means, those who are giving much labour and valuable time to the organisation of research, as well as to those who consent to devote their whole lives in endeavouring to determine what so far has proved to be one of the insoluble problems of human life?

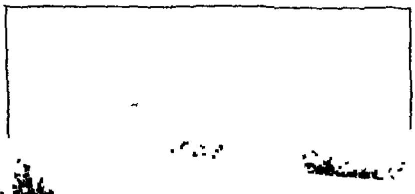
The proceedings then terminated

FRUIT AND FILTH.

(FROM A CORRESPONDENT)

To the uninitiated fruit picking calls up pleasant mental pictures of picturesque crowds of country people in sun bonnets and bright coloured aprons, with laughing eyes and brown faces, coming home laden with baskets of the rich, red strawberries or the even more brilliantly coloured red currants or other tempting fruit—all clean and sweet and wholesome As a matter of fact the true state of the case is very different, the greater part of the fruit that comes to London is picked and handled for market and made into jam by the very filthiest people in the whole community There are exceptions here and there, but I am well within the mark in saying that the greater proportion of the fruit grown in Kent is picked by people whom the readers of this article literally would prefer not to touch even with a pair of tongs Beginning at Orpington and the Crays and going south and east through the fruit-growing districts the observer will see at intervals of a mile or two long rows of iron shanties, each about 7 feet by 13 feet, which, did he not know, he would probably consider to be a particularly bad kind of pig sty and he would reflect and possibly write letters to the newspapers upon the great increase in pig keeping in Kent (Fig 1) He might also, if he were of an altruistic turn of mind comment upon the cruelty of keeping pigs during the hot weather in boxes made of corrugated iron In sober truth these are the dwellings of the people who pick the fruit or, to be strictly accurate, the greater part of it As soon as the strawberries commence to ripen the very lowest of the slum dwellers move out along the country roads into Kent and take up their abodes in the corrugated iron shanties ready for the fruit picking A few of the more aristocratic bring tents in which I have even seen a bed, whilst a still smaller proportion come in caravans The pickers, or, to give them their Kentish appellation, "pykers," who live in caravans, would amount to certainly not more than 1 per cent and the tent-dwellers might be reckoned in about the same proportion, the great majority live in the shanties They all belong to the floating, wastrel population who live by doing odd jobs and sometimes make pretty nearly enough during the summer at fruit-picking and hop picking to carry them through the winter season As soon as the soft fruit season is over they move farther down into the country to pick the hops The filthiness of the hop pickers is proverbial, but the fruit pickers are as filthy as any of the hop pickers, in fact, they form the lowest stratum, as many of the better-class hop pickers come down for the hop picking alone, regarding it as a yearly holiday

FIG. 1.



A view of the pickers shanties

On entering one of the little 13 feet by 7 feet dwellings, as well as you can on account of the crowd of urchins—bare footed, ragged and unwashed, with bright eyes *peeping* through matted hair and looking perhaps all the brighter from the long standing dirt on their faces—you will see probably one or two boxes turned up on end for seats and along one side bunks formed of strips of coarse canvas suspended one over the other as they are on board ship The people pack pretty closely and, including children and babies, there are generally six or eight human beings occupying one shanty My *wife tells* me that she has seen as many more people huddled up in one of these shanties in the winter, but they could hardly have all *slept* in one of them I may mention that my wife was obliged to discontinue her investigations on account of the fleas which she

every occasion, "not in single

A considerable number of the

wretched shanties all the year rou

at all events, getting a few odd jobs in the fields and at sorting potatoes, but living to some extent on the savings which they have made from the fruit season As may well be imagined, the sanitary arrangements are of the most elementary description, although as the people are living in the open air, usually removed at some distance from other dwellings, it may not be a matter of very great importance, but their general condition is indescribably wretched On my last visit to one of the Swanley "compounds" I watched a picker woman, having done her day s work in the strawberry fields, seated on a box and searching for lice in the tow coloured hair of a little girl who was kneeling in front of her This woman must have belonged to the aristocratic and cleanly section, for I am quite certain that the majority of them would not trouble themselves about such trifles as this

There are usually two pickings of strawberries and other soft fruit every day except Saturday and Sunday during the season the first as soon as there is sufficient light to see to pick the fruit commencing, say at 3 30 A M, and the second during the morning The first picking serves for the early trains which leave between 6 and 8 A M for the London market and the second picking for the London market to a certain extent and for the fruit trains which go to Manchester and the North For the first picking the "pykers" tumble out of their bunks—men, women, and children—and hasten to the adjoining fields They are provided with small chip baskets, which are emptied into larger baskets placed at the ends of the rows or in other convenient situations, and are paid at piece rates Most of the "pykers" have large families and they all help in the picking as soon as they are old enough to toddle In a good season a family will make quite good wages whilst it lasts, which is not for more than two months altogether, some families making as much as £2 per week As their expenses need amount to very little some of the more thrifty manage to put by (for them) a substantial sum When the larger measures are filled they are taken to a shed where the overseer gives tallies in exchange for them I have frequently stood by whilst this operation has been going on and if I have been on the leeward side the smell which has come from the crowd round the shed, in spite of the beautiful odour of the fruit has been horrible A few days ago I took shelter from a passing shower under a tree where a number of pickers had stood with their baskets about an hour previously and even after that *length of time the smell* was so evil that I preferred to move through the heavy rain to another tree some way off We hear a great deal about the filthiness of Poles and Russian Jews but I feel quite sure that it would be impossible for any people to be filthier than are those who pick the fruit in Kent (Fig. 2). Outbreaks of typhus fever, although not common, have occurred amongst them in recent years, and probably if it were possible to secure the statistics from the different districts some very alarming figures might be shown, although the life in the fresh air must do much to minimise the risk of epidemic disease. In picking the fruit the fingers of these people come into most intimate contact with the berries, and in the case of raspberries, which are of a very "squashy" description, the fruit must form almost a solution of the dirt on the fingers of the pickers. No country people in the fruit districts, however poor, would touch fruit which has been handled by the pickers and most careful inquiries are always made as to who has picked any fruit offered for sale. Yet a very large proportion of the fruit gathered by these filthy people must pass to the houses not only of the average respectable middle-class person but to the tables of "the rich and the great."

Swanley is perhaps the centre of the soft fruit district and a more wretched place it would be difficult to find. It consists essentially of one long street separated by two little streets from a large manure siding. There is no main drainage, the cesspool system being in use. As this is combined with a high-pressure water-supply the sanitary condition of Swanley during the fruit season may well be imagined. The extra pressure of population proves too much for the cesspools and I have frequently seen the liquid contents flowing down the gutters of the main street. The overcrowding, however, is not so bad as it was, for within the last year or two several rows of cottages have been erected on the outskirts. To get over the cesspool difficulty many of the cottage owners have driven deep holes into the chalk, which is only a few feet down, with the consequence that the sewage drains away through the chalk and the cesspools do not require to be emptied. The prospect of sewage finding its way into the Kent Company's water-supply which is drawn from the chalk is, to say the least, are a large number of these pickers the Swanley district and the photographs which are reproduced here have been taken near Swanley. The total number of corrugated iron shanties within two miles of Swanley station must amount to many hundreds and the fruit pickers in that neighbourhood are perhaps the filthiest in Kent; although I came across a large crowd near Orpington who would run them very close. The pickers at Hockenden, near St. Mary Cray, seemed of a slightly cleaner description, but there was not much to choose. In very few cases is the water laid on to the pickers' compounds and they have to fetch all they want in buckets, frequently from a distance, so that they have no temptation to be cleanly, even if they were so disposed. In the Wrotham district and near Tonbridge a large proportion of the picking is done by genuine country people and a very pretty appearance they present, but there is one farmer near Ightham who employs as wretched and filthy a set as can be seen anywhere. On the south-east side of Ightham also there are some very bad compounds.

It is interesting to trace the fruit from the fields on its way to the jam-pot. Not long ago I had the opportunity of going through a large London jam factory. As the fruit was delivered from railway wagons and the firm's own vans it was handed over to dirty old women to pick off the stalks and again went through a large amount of unsavoury handling. Then part of the fruit was made straight into jam by boiling it in steam jacketed pans with sugar. When the jam was sufficiently concentrated it was ladled into jars and allowed to cool in the usual way, whilst another portion was "pulped," that is to say, the fruit was partly boiled so as to sterilise it, and then packed away in large jars in the basement to be made into jam during the slack season. The soft fruit season is so short that some jam makers prefer to do this but the quality of the pulped jam cannot be nearly so good as that of the freshly made. Nevertheless, it enables a much larger quantity of jam to be made with the same plant and the factory goes on steadily until the marmalade season commences. The workers in this factory were certainly a little cleaner than the fruit pickers but were still of a very miserable, unwashed description. I feel sure that anyone who had seen the way in which fruit is handled would require a warranty from the jam maker that the fruit had been picked by cleanly people and made into jam by decent folk. As a contrast to this I may mention another visit to a jam factory in Cambridgeshire where the fruit was picked by the country folk and made into jam under the best conditions and I have no doubt that there are others equally as good.

FIG. 2.

A group of pickers.

I fear that it is very difficult to suggest a remedy for this very unsavoury state of affairs. It arises from the depopulation of the country districts and until through some alteration in our land system and other conditions the population is restored it seems to me that the farmers will be largely compelled to rely during the busy season of fruit-picking upon the wretched folk I have described. As I mentioned above, the overcrowding in the Swanley district has been remedied to some extent but in the Wrotham district matters seem to be going from bad to worse. As cottages become uninhabitable they are not replaced and a considerable number of cottages have been used by the local landowners for conversion into villas by the addition of another two or three rooms thus literally driving the peasantry out of the country." It would be difficult to animadvert too strongly upon the overcrowding which has been needlessly caused by the landlords round Ightham Whilst this goes on it is hopeless to expect any improvement in the conditions under which fruit is picked At the [illegible] t the farmers and land owners ([illegible] lutely callous about the matter ([illegible] the district and county councils the sanitary authorities apparently do not trouble themselves about the present state of affairs

HYGIENE AND TEMPERANCE FOR ELEMENTARY SCHOOLS

THE important petition signed by 14 718 registered medical practitioners in the United Kingdom addressed to the central education authorities asking that teaching on cleanliness, pure air, food, and drink should be included in the curricula of the public elementary schools and encouraged in the secondary schools was presented to Lord Londonderry, President of the Board of Education, at the offices [illegible] London, by a deputation of the [illegible] dical profession on July 11th [illegible] they are well aware that the laws of health may receive attention in the schools at the present time but that it is an optional subject They believe that it should be compulsory and that the instruction should be given at a much earlier age than at present The petitioners also urge the central education authorities to instruct the school children concerning the effects of alcohol on the body and the mind, and a strong point is also made of the necessity of insuring an adequate training of school teachers in regard to hygiene, temperance, and sanitation

The deputation was introduced to Lord Londonderry by Dr R Farquharson, M P, who is chairman of the Public Health Committee of the House of Commons The first speaker called upon was Sir William Broadbent, who has taken an active part in the movement and has done a great deal of work as chairman of the committee of distribution of the petition and who detailed the active efforts of the medical profession in furthering the development of early training in the principles of hygiene and temperance He was followed by Dr T D Griffiths President of the British Medical Association, who referred to the action of the Association and read a resolution passed by the council of the Association in January last strongly supporting the present movement as a practical measure against national physical deterioration and describing the general interest of the Association in the education of the people in hygiene and temperance Sir Thomas Barlow then made a short speech in which he urged the central authorities in education to adopt the proposed development of elementary education in hygiene and temperance and he then proceeded to explain what the far reaching effects of such teaching would be on the health and social prosperity of the nation The next speaker was Dr C F Hutchinson M P, who mentioned that it gave him great pleasure to support the deputation as he was one of the members of the Public Health Committee of the House of Commons He promised the medical profession that the movement would be helped in the House of Commons if medical men continued their efforts Professor G Sims Woodhead made a good point in the short speech which he delivered by emphasising the importance of the subject being taken up and directed in a thoroughly organised fashion by the central education authorities Sir Lauder Brunton discussed the matter from the wider standpoint of its international character and commented on the importance of cons [illegible] lrawn from the International [illegible] held at Nuremberg Dr M [illegible] ed of elementary teaching of hygiene, particularly in respect of the diet and feeding of infants and children, and remarked on the influence that such teaching would have on national hygiene and the spread of temperance Sir Victor Horsley was the last speaker on behalf of the deputation and he drew particular attention to the desire of the medical profession that the Government should institute elementary education in principles of health and temperance He declared that the necessity had been proved for such teaching being made universal and succeeded in showing very plainly how important it was to train the school teachers in the principles of hygiene, temperance, and sanitation

Lord Londonderry, in his reply, explained what the Board of Education had done and was intending to do towards carrying out the wishes of the deputation He was as anxious as Sir Victor Horsley was to have teachers giving instruction in the subject of hygiene but he was bound to say that at the present time those teachers did not exist It was impossible to believe that anyone would wish the children to be instructed in such important subjects by those who were not properly trained The Board of Education was however, devoting itself to the training of such teachers and he trusted that in the course of time its efforts in that direction would bring about the desired result The petition referred to the serious physical and moral conditions of degeneracy and disease resulting from the neglect and infraction of the elementary laws of hygiene, but he called their attention to the fact that a competent committee had for some time past been investigating the alleged effects of physical deterioration Until he was in possession of the opinions of that committee he felt that his hands were tied If when the committee reported they learnt that the evil suspected to exist was of a distinctly local character then he hoped that the action which the Board of Education had already taken in regard to instruction in the laws of health would prove to be sufficient to place the question everywhere on a proper basis in a short time Lord Londonderry concluded by quoting from the regulations and code issued by the Board of Education and asked the deputation to believe that the educational authorities were not ignoring the important questions raised by the petition He assured them that they fully realised their responsibility for contributing towards the production of a race that was strong in health and intellectually competent

MEDICINE AND THE LAW

Alleged Negligence in the Use of Cocaine

A VERDICT for the defendant has at last concluded an action brought against Mr Ebenezer Apperley a dentist practising at Stroud and in London which arose out of an operation performed in 1902 The plaintiff a carpenter, went to Mr Apperley's surgery on Christmas Eve suffering from toothache and the defendant's son also a dentist inserted a temporary stopping of cotton prepared with oil of cloves carbolic acid carbolised resin, and cocaine lanoline For this according to his evidence he used a 10 per cent solution of cocaine and he stated that he was sure that he did not put more than one twenty fifth of a grain of cocaine into the tooth The immediate effect upon the plaintiff according to his account of the matter was to make him dizzy so that he reeled like a drunken man On the following day when he was eating some pudding the temporary stopping came out and he swallowed it This according to his story, gave him ' another turn and he became so ill that a medical man was called in The plaintiff appears to have believed that the cotton wool was impregnated with cocaine only and in the course of the trial medical witnesses expressed the opinion that his symptoms were consistent with cocaine poisoning Medical witnesses for the defendant, besides the gentleman who put in the temporary stopping, negatived the alleged negligence, expressing the opinion that the temporary stopping had according to the plaintiff's own evidence, been properly inserted Attention was also called to symptoms among those described which were inconsistent with cocaine poisoning and to the absence of others which might have been expected The medical witnesses for the defendant considered that the sufferings of the plaintiff spoken of by himself and others and ascribed to Mr Apperley's alleged negligence were due to epilepsy or hysteria and this view was no doubt that of the jury The defendant is to be congratulated upon the result of the protracted litigation of which he has been the victim An action of such a description inflicts serious hardship upon a professional man who even if he is ultimately successful in defending his reputation can only do so at considerable expense and after enduring much anxiety The defendant in short, is at the mercy of the plaintiff for as long as the latter chooses to go on the former has no alternative but to resist the claim. To yield would be to admit a charge of professional incapacity and the contest is often with one who has everything to gain and little or nothing to lose by continuing it.

Nurses and Children.

The medical evidence given in a recent prosecution at the Marylebone police-court should be a warning to parents who intrust their children to the care of nurses that careful supervision is necessary in all cases, even when the usual testimony to good character has been obtained and the servant engaged appears to fulfil her duties satisfactorily. Ada Sprague, a girl, aged 19 years, summoned by her master for assaulting his son, aged three years, claimed to have had a gold watch given to her by her former employer and a ring by the prosecutor, and mentioned these somewhat unusual gifts to prove that she had not been altogether a bad nurse. Dr. J. Maughan, however, the divisional surgeon of police who had examined the child, deposed to bruises on his cheek, forehead, eyelid, and temple, to six bruises in the left groin, two in the region of the loin, and many others on the arms and other parts of the body. He had counted over 60 in all, independently of a mass of marks between the shoulders too numerous to be distinguishable, and he was able to say that though no individual injury was serious the effect of the thrashing which the child had received had been to produce a shock which prevented him from attending the court. The servant admitted that she had lost her temper with the little boy and alleged that he was dirty and stubborn. Mr. Plowden, the magistrate, referring to her statements mentioned above as to the esteem in which she has been held in her situations as nurse, said that the only surprise he felt was that she should be intrusted with the care of children at all and fined her 40*s*. with the alternative of a month's imprisonment. The father of the child is to be congratulated upon having secured this young woman's conviction and upon having laid before the bench clear and independent evidence in support of his charge. Not a few children suffer seriously in mind and body from the heedless unkindness or deliberate cruelty of their nurses. Those who observe the conduct of the women in charge of the children of the wealthier classes in such places of public resort as Hyde Park and Kensington Gardens cannot fail to notice at times instances of harsh treatment, such as to cause wonder whether the parents are aware of what goes on in their absence. In many cases they are not so aware and information given by the onlooker would be welcomed with gratitude; in others they are not only ignorant but indifferent; and in some the treatment meted out to the unfortunate little ones is actually connived at, or approved of, by persons who would resent as impertinent any report made to them or any remonstrance with their servant. The excuse made by the nurse that the child was "dirty" recalls a similar one put forward by Mrs. Penruddocke at the Old Bailey before her conviction for cruelty to her own child. It is not only temporary pain but actual injury to health that is inflicted upon children of tender years by chastisement when gentle and patient training and possibly medical advice are required.

Death Certification by an Unqualified Person.

At Winchester assizes a man charged as Charles Henry Hustwick alias Cormac has been convicted and sentenced to 18 months' hard labour for feloniously giving on the prescribed form issued to medical men a certificate of the death of a child. It was proved that the prisoner's name was not, and never had been, on the Medical Register, in spite of which he impudently asserted his innocence of the charge and boasted of having practised as a medical man for many years, having apparently at one time acted as an unqualified assistant to medical men. After the jury had given a verdict against him a previous conviction was proved for an attempt to procure abortion in Devonshire. It is to be hoped that the police will keep a watchful eye upon this person upon his release.

HEALTH OF ST. IVES.—The medical officer of health of St. Ives, Cornwall, in his annual report for 1903, states that the population of the town is 6697 and that 175 births were registered, giving a birth-rate of 26·13 per 1000; 95 deaths were registered, giving a death-rate of 14·18 per 1000.

Looking Back.

FROM

THE LANCET, *SATURDAY*, JULY 15, 1826.

HOSPITAL REPORTS.

ST. BARTHOLOMEW'S HOSPITAL.[1]

Dr. Latham, in reference to the above interesting case of hydrophobia, expressed in the presence of Mr. Abernethy, Mr. Vincent, and Mr. Stanley, and a numerous assemblage of pupils, an anxious wish for a post-mortem examination; observing at the same time his doubts of its practicability, as it was a notorious fact that the beadles were not only grossly deficient in their duty, but that it was against their interest to allow any examination whatever. Mr. Vincent mildly inquired of a beadle (a fellow of the name of Gates,) if there were any precise time for the corpses of patients to remain in the ward, where their influence must prove injurious to the unfortunate and distressed beings condemned to such a charnel-house; and if such regulation did exist, did it extend the time to five or six hours after death?

The beadle answered in a manner peculiarly his own, "*that in many instances they remain the whole of the day!* and as to any regulation he knew nothing about it."

Mr. Vincent expressed his disapprobation, and demanded a second time, to know if there was any such rule; remarking that it was disgraceful conduct, and very unfeeling to the poor friendless patients.

Mr. Stanley condescended to reason with the fellow, and thinking the argumentum ad hominem most fitted to his capacity, asked how he should like to be condemned to lie on a bed of suffering contiguous to a putrefying dead body for such a space of time? To this question the man of feeling (viz. the beadle) very properly and sensibly said that he would not like it at all. Dr. Latham desired to know, (as no rule had been laid down by the Governors of the hospital, and as it seemed to be left entirely to the humane discretion of the beadles,) the usual time they, in the exercise of that discretion, allowed to elapse before it pleased them to remove the putrefying mass, and whether he, the said Gates, considered himself fulfilling his duty to his employers, by allowing it to remain five or six hours, nay even the whole day, in the ward, during such African or dog-day weather as we now experience? The omnipotent beadle, being learned in the law, was aware that if he spoke the truth he would stand self-convicted, determined on being insolent, thereby avoiding a disagreeable answer to a question (in his opinion) *most uncalled for and unnecessary*. Screwing therefore his courage to the sticking place, he cooly informed the Doctor "that as the conversation commenced with Mr. Vincent, he did not *think fit* to answer *him*."

Dr. Latham turning to the pupils said, "You see Gentlemen, how these men domineer over the medical men; they do so to me every day. ...... It is a notorious fact, and the committee themselves know it, that every individual beadle in this hospital is an undertaker, and I ask, are undertakers fit men to fill the situation? Instead of doing their duty to the hospital, it is their interest to permit the friends of the deceased to take away the bodies. It would be both expense and trouble to the beadles to remove them to the dead-house; and by waiting for the relatives, and keeping the corpse in the ward, they stand a fair chance of becoming UNDERTAKER at the funeral. The committee shall be informed of this."

Mr. Stanley then expressed his wish to accompany Dr. Latham and Mr. Vincent to the committee; he said he had another cause of complaint against Gates to make known to the committee.

The fellow with an air of defiance and insolence, which he preserved throughout, told them he should be ready to answer them, and walked off.

Dr. L. addressing the pupils, said, "Gentlemen, as this is a most interesting case, and you will be most anxious to be present at the examination, I am sorry to say that it is out of my power to promise you any thing on that point, but I think I can name one way: '*Bribe* the beadle, Gentlemen, *bribe* the beadle.'"

---

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8567 births and 3948 deaths were registered during the week ending July 9th The annual rate of mortality in these towns which had been 13 8, 13 2 and 13 5 per 1000 in the three preceding weeks, was 13 5 per 1000 again last week In London the death rate was 12 9 per 1000 while it averaged 13 7 per 1000 in the 75 other large towns The lowest death rates in these towns were 2 6 in Handsworth (Staffs), 3 2 in Hornsey, 6 3 in King s Norton 6 9 in Tottenham, 7 1 in Leyton, 7 7 in Cardiff 8 4 in Walthamstow, and 8 5 in Coventry, while the highest rates were 17 7 in Gateshead, 17 9 in Manchester, 18 0 in South Shields 18 2 in Liverpool, 19 1 in Oldham 19 9 in Stockport 21 1 in Burton on Trent, and 21 4 in Huddersfield The 3948 deaths in these towns last week included 500 which were referred to the principal infectious diseases, against 487, 444, and 455 in the three preceding weeks, of these 500 deaths 182 resulted from measles, 115 from diarrhœa 109 from whooping cough, 40 from diphtheria, 32 from scarlet fever, 16 from ' fever ' (principally enteric), and six from small pox No death from any of these diseases was registered last week in Hornsey, Bournemouth, Devonport Handsworth (Staffs), Kings Norton, Wigan, Stockton on Tees, West Hartlepool, or Merthyr Tydfil, among the other towns the highest death rates from the principal infectious diseases were recorded
Liverpool, St Helens
Huddersfield The gr[illegible]
measles occurred in Walthamstow Plymouth Birkenhead Liverpool, St Helens Salford, Oldham, Burnley, and Huddersfield,, from scarlet fever in Aston Manor and York, *from diphtheria in Grimsby, from whooping* cough in Great Yarmouth, Burton on Trent, Birkenhead, Warrington, and Blackburn, and from diarrhœa in Southampton and Gateshead The mortality from 'fever ' showed no marked excess in any of the large towns Of the six fatal cases of small pox registered in these towns last week five belonged to Stockport and one to Gateshead The number of small pox patients under treatment in the Metropolitan Asylums Hospitals, which had been 80, 83, and 74 at the end of the three preceding weeks, had further declined to 71 at the end of last week, 10 new cases were admitted during the week, against seven, 16 and 10 in the three preceding weeks The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday last, July 9th was 1685 against 1630, 1629 and 1631 on the three preceding Saturdays, 269 new cases were admitted during the week, against 206, 199, and 254 in the three preceding weeks The deaths in London referred to pneumonia and diseases of the respiratory system which had been 142, 141, and 146 in the three preceding weeks declined again last week to 135 but were eight above the number in the corresponding period of last year The causes of 41 or 1 0 per cent of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Nottingham Salford Bradford, Newcastle on Tyne and in 51 other smaller towns, *while the largest proportions of uncertified deaths were* registered in Northampton Norwich, Birmingham Liverpool, Bolton, Sheffield, and Sunderland

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns, which had been 17 0 15 9 and 16 3 per 1000 in the three preceding weeks declined again to 15 8 per 1000 during the week ending July 9th, and was 2 3 per 1000 in excess of the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 12 3 in Perth and 13 0 in Aberdeen and in Leith, to 16 5 in Glasgow and 17 5 in Dundee The 524 deaths in these towns included 24 which were referred to whooping cough, 20 to diarrhœa, seven to ' fever ' six to measles, three to small pox two to scarlet fever, and two to diphtheria. In all, 64 deaths resulted from these principal infectious diseases last week, against 66, 74, and 75 in the three preceding weeks These 64 deaths were equal to an annual rate of 1 9 per 1000, which was 0 2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns The fatal cases of whooping cough, which had been 21, 27 and 31 in the three preceding weeks, declined again last week to 24, of which 13 occurred in Glasgow, six in Edinburgh, and four in Aberdeen The deaths from diarrhœa, which had been 20, 22 and 18 in the three preceding weeks, rose again to 20 last week and included ten in Glasgow, three in Dundee *two in Edinburgh, and two in Aberdeen The fatal cases of* fever, which had been two, four, and three in the three preceding weeks increased again last week to seven of which four (including one from typhus) were registered in Glasgow, and two in Edinburgh The deaths from measles, which had been 12 and 14 in the two preceding weeks, declined again to six last week, and included two in Glasgow and two in Leith The fatal cases of small pox, which had been three one and two in the three preceding weeks rose again last week to three of which two were recorded in Glasgow and one in Edinburgh The deaths referred to diseases of the respiratory organs in these towns, which had been 93 64 and 80 in the three preceding weeks further rose last week to 88 but were slightly below the number in the corresponding period of last year The causes of 18 or more than 3 per cent, of the deaths registered in these eight towns last week were not certified

HEALTH OF DUBLIN

The death rate in Dublin which had been 21 7, 19 5, and 16 5 per 1000 in the three preceding weeks, rose again to 17 9 per 1000 during the week ending July 9th During the past four weeks the death rate has averaged 18 9 per 1000 the rates during the same period being 12 9 in London and 16 1 in Edinburgh The 130 deaths of persons belonging to Dublin registered during the week under *notice showed an excess of 10 over the number in the* preceding week and included 10 which were referred to the principal infectious diseases, against six, three and seven in the three preceding weeks, of these, five resulted from diarrhœa three from whooping cough, and two from measles, but not any from small pox, from scarlet fever, from diphtheria or from "fever' These ten deaths were equal to an annual rate of 1 4 per 1000 the death rates last week from the principal infectious diseases being 1 5 in London and 2 0 in Edinburgh The deaths from measles corresponded with the number in the preceding week while those from whooping cough and from diarrhœa showed an excess The 130 deaths in Dublin last week included 22 among children under one year of age and 33 among persons aged 60 years and upwards, the deaths both among infants and among elderly persons slightly exceeded the respective numbers in the preceding week One death from violence and three inquest cases were registered, and 45 or more than a third, of the deaths occurred in public institutions The causes of ten, or nearly 8 per cent, of the deaths in Dublin last week were not certified

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following appointments are notified —Fleet Surgeon O W Andrews to the *Magnificent* Surgeons F Cock to the *Magnificent* and A A Forrester to the *Pembroke* to be lent to Chatham Hospital

ROYAL ARMY MEDICAL CORPS

Major J W F Long retires on retired pay (dated July 9th, 1904) Captain E C Hayes and Captain I H M Clarke have been appointed to the Home District for duty in London

INDIAN MEDICAL SERVICE

The King has approved of the following promotions in and admissions to, the Indian Medical Service —Bengal to be Colonel Lieutenant Colonel David Wilkie (dated April 2nd 1904) Majors to be Lieutenant Colonels John Henry Tull Walsh Harold Hendley Hormasji Edulji Banatvala and William George Patrick Alpin (dated April 1st, 1904) To be Lieutenants Charles Hildred Brodribb (dated August 31st 1903) Punjab Hugh Basil Drake, Ernest Charles Hodgson William Sim McGillivray William Gillitt, William Frederick Brayne, Charles Harrison Barber, Hugh Watts, and William Tarr. Bombay: Merwan Sorab Irani, Ivor Davenport Jones, Walter Taylor Finlayson, Seymour Whitworth Jones, William Thomas McCowen, Hugh Ellis Stanger-Leathes, and John Anderson. Madras: Edmund Arthur Roberts, Geoffrey Gratrix Hirst, Michael Joseph Quirke, John Morgan Holmes, and Maurice Forbes White (dated Jan. 30th, 1904).

The King has also approved of the retirement from the service of the undermentioned officer: Lieutenant-Colonel John Campbell Fullerton (dated June 25th, 1904).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Glamorganshire: Francis Griffith Thomas to be Surgeon-Lieutenant (dated July 9th, 1904). 8th Lancashire: Charles Edwin Maximilian Lowe to be Surgeon-Lieutenant (dated July 9th, 1904).

Rifle: 3rd Volunteer Battalion the Devonshire Regiment: Surgeon-Captain W. Langran resigns his commission (dated July 9th, 1904). 2nd (Berwickshire) Volunteer Battalion the King's Own Scottish Borderers: Surgeon-Captain S. Macvie to be Surgeon-Major (dated July 9th, 1904). 2nd Volunteer Battalion the Durham Light Infantry: Brigade Surgeon-Lieutenant-Colonel T. A. McCullagh resigns his commission and is granted the honorary rank of Surgeon-Colonel, with permission to wear the prescribed uniform, vacating at the same time the appointment of Senior Medical Officer to the Durham Light Infantry Volunteer Infantry Brigade (dated July 9th, 1904).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Woolwich Companies: Lieutenant J. Hardie to be Captain (dated July 9th, 1904). Welsh Bearer Company: Captain A. W. Sheen is appointed to command (dated July 9th, 1904).

THE SOUTH WALES BORDER VOLUNTEER INFANTRY BRIGADE.

The brigade camp will be held during July and August at Salisbury Plain and will consist of the following regiments—viz., the 1st, 2nd, 3rd, 4th, and 5th V.B. South Wales Borderers and the South Wales Border Volunteer Infantry Brigade Bearer Company. Surgeon-Captain R. J. Paton has been promoted to Surgeon-Major and Mr. D. J. Thomas has been appointed Surgeon-Lieutenant. Brigade Surgeon-Lieutenant-Colonel Philip E. Hill, V.D., is the senior medical officer of the brigade.

THE WAR IN THE FAR EAST.

It is very difficult to follow the progress of the war or to form anything like a correct estimate of the strength of the forces that have taken part in the latest military operations or of the losses sustained on either side; nor is it easy to locate at the present time their relative positions to one another in the field with a view to obtain some idea of their future strategical aims and movements. No decisive battle has yet been fought, but everything points to one being imminent, possibly at Tashi-chao or Newchwang. It seems certain, however, that the Japanese have taken and occupied Kaiping after some hard and protracted fighting, that the siege of Port Arthur is being actively carried on, and that there has been a good deal of almost continuous fighting in its vicinity, the fleet coöperating with the land forces. We have but little to do, however, with this aspect of the war, and from a purely medical point of view there has been next to nothing to record during the past week. The Japanese troops owing to their occupying for the most part mountain passes, rising ground, and the slopes of hills have obviously a better sanitary position in the rainy season than the Russians located on the rain-sodden and more or less water-logged plains, and it would be both interesting and instructive to have some statistical evidence of even an approximate kind about the relative sickness of the two armies. As regards the number of killed and wounded in the various recent engagements there is a wide disparity between the official estimates that have been published in the Russian and Japanese despatches. With regard to the Russian army we learn through Reuter's Agency that the *Official Messenger* has published the following telegram from Tashi-chao regarding the health of the Russian troops in the field: "Up to June 26th the number of officers and men in hospital amounted to 7·136 per cent. and 3·943 per cent. respectively of the total forces. If the wounded officers and men already removed to the rear are included the percentage is 10·24 and 6·51. After the beginning of the rainy season on July 9th the percentage of officers and men in the hospitals rose to 8·384 and 4·646 respectively, the proportion of patients suffering from infectious diseases increasing from 2·19 per cent. to 8·52 per cent., including a percentage of dysentery cases of 1·99." With a single line of railway and the amount of war material and food, as well as the number of reinforcements that have to be conveyed along it, we do not see how the Russians can carry out the system now adopted in warfare of transporting the sick and wounded from front to rear as soon as possible, and so far as Port Arthur is concerned the difficulty of providing them with medical relief and hospital accommodation must prove well-nigh insuperable. In this connexion we may mention the report of the senior medical officer of the *Mongolia* hospital ship at Port Arthur, who says that it is difficult to count on the complete recovery of the sick and wounded in Port Arthur unless they can be removed. The continuous tension is hard on them; every bombardment makes their condition worse, and the *Kotlin* suggests that the *Mongolia* should be allowed to take its invalids to Shanghai to tranship them for Russia.

The Liaoyang correspondent of the *Torgovo Promys-schlennaya Gazeta* sends the following description of the deplorable state of Inkau (the port of Newchwang). After describing the danger from the Chungtchuses, he says: "Not less dangerous for the town are the epidemic diseases which begin every year in the town and spread along the populous routes of Manchuria right through Transbaikalia to Irkutsk and Krasnoyarsk along the line of the Siberian railway. It may be said that Inkau has served as the home of plague and cholera that have raged in the Far East for a considerable period yearly, and probably the premier position as propagator of these diseases is reserved for that town for a long time to come. The sanitary condition of the town is fearful. Thousands of Chinese coolies live there in a state of extreme poverty and make use of food that has not had the slightest sanitary inspection. They inhabit houses that do not answer to the most rudimentary idea of hygiene. The deep river Liaoho which runs past the town is choked with refuse of all kinds which with the ebb and flow of the tide keeps moving in front of it. The river water is good neither for drinking nor washing by reason of its filth. Nevertheless, the Chinese who live on the junks make use of it. Besides this there is the large Chinese cemetery at a short distance from the town where the victims of previous epidemics are buried at such a little depth from the surface that wind blowing from that direction carries the effluvia of the corpses through the town. The principal European settlers in Inkau are English, Americans, and Germans and the Russians are the least in number."

THE JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The July number of this publication, edited by Colonel David Bruce, F.R.S., R.A.M.C., contains many excellent papers and more than maintains its scientific and literary interest. Among the original communications the articles on Enteric Fever by Captain E. Blake Knox, R.A.M.C., and by Captain W. S. Harrison, R.A.M.C., are well worth reading. The former deals with the spread of enteric fever by urine and its prophylaxis and the latter with our present position with regard to enteric fever in India. Colonel Bruce contributes a paper on Sleeping Sickness in Uganda which is admirably illustrated and, as might have been expected from its source, is of high scientific value. The author deals with the subject in an ably reasoned and exhaustive way. The journal contains other papers of scientific, clinical, and general interest such as one on the Infectivity of Scarlet Fever by Lieutenant-Colonel R. H. Firth, R.A.M.C., and articles on the Medical Services of the Russian Army and on medical and surgical cases. But we must not omit to mention that under the heading of "Echoes from the Past" there appears Part I. of some charming notes written in fresh and simple style of Queen Victoria's visit to Fort Pitt and Chatham contributed by George Russell Dartnell, deputy inspector-general of hospitals, 1855-56.

THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on July 12th with Sir James N. Dick, K.C.B., in the chair, the sum of £60 was distributed among the several applicants.

Correspondence.

"Audi alteram partem"

THE THORNE DEFENCE FUND

To the Editors of THE LANCET

SIRS,—May I express through the medium of THE LANCET my most grateful thanks for the chivalrous and practical sympathy which has been shown to me by colleagues and friends, known and unknown, in relieving me of the costs and damages awarded against me in the recent action in which I was the defendant? The sympathy has been most grateful to me and has very much helped me to bear the strain and anxiety inevitable in a case where one's professional character has been assailed I should also like to express my indebtedness to the Medical Defence Union and to Mr Hempson, the solicitor to the Union, for the care with which this case was conducted

I am, Sirs, yours faithfully,

Harley street W, July 12th 1904 MAX THORNE.

THE PRESENT CONDITIONS OF INFANT LIFE AND THEIR EFFECTS IN REGARD TO THE INFANT, CHILD, AND ADULT

To the Editors of THE LANCET

SIRS—It is a mere truism to say that we are entirely dependent on the infants of the present for the adult population of the future Yet while we do much to deal with disease in the child and adult we are almost totally neglecting to care for the human being at a period of life when exceptional care is most urgently needed About one fourth of the total deaths at all ages are contributed by infants under one year of age This mortality is extremely excessive It appears even more so *when we remember that all* the infants in the land are
so that those cared for in
and of the wealthy tend
homes of the poor Deal
Dr E W Hope medical officer of health of Liverpool wrote *in his report for the year 1901* —

> In the course of an inquiry into infantile mortality 1082 families in which the death of an infant had occurred were taken consecutively
> ine l The total
> n 4574 but out of
> ncy—representing
> markable series of
> the large total of
> rished in infancy
> These extreme examples occurred in families in which so far as municipal sanitation is concerned there was very little to choose between them and many of the families who rear all or nearly all their children

The mortality is bad enough but it must be doubted whether this is the worst result What of those who escape death? Do the survivors emerge uninjured by the conditions responsible for the death of so many of their fellows? Mr W Hall of Leeds has supplied one instance of the answer to this question Out of 2335 board *school* children examined by him he found that more than half were rickety But it is idle to select instances when the results are devastating the country It is scarcely credible that the present situation can continue when the medical profession and the public understand the issues involved *The study of* the infant and the conditions of infant life have been almost totally neglected and disease and deformity of every kind are the legacy of our neglect Year by year the demand for hospital accommodation increases and we persistently shut our eyes to the real and preventable cause of this demand *No matter whether we turn to hospitals for diseases of the* nervous system or to hospitals for diseases of the chest we see the results of infantile malnutrition In the wards and in the out patient departments of practically every general and special hospital we see the same thing The asylums, *prisons and workhouses are largely dependent for their* inmates upon the mental and physical deformities arising from defective structure

The predominating primary cause of these conditions is the improper feeding of the infant Maternal nursing is the ideal method and everything should be done to encourage this under proper conditions But this method is impracticable in a very large number of cases and consequently substitute feeding becomes a necessity The great reason for the present conditions is that the physiological factors involved have been almost completely neglected To obtain any real improvement it is essential that the traditional and domestic methods of artificial feeding should be entirely abandoned To discuss these methods in detail would be far beyond my present purpose Their failure is writ large in the present state of affairs Unfortunately the problem has been rendered more complicated by the well meant efforts of some of our municipalities to deal with the situation Stock mixtures put up in bottles and then sterilised may do a good deal *to diminish the mortality in the first year* But such a benefit may be dearly purchased The lessening of the mortality by such means must be followed by disease and deformity in the later years resulting from patent defects in the food mixtures supplied and the destruction of *important properties by the process of sterilisation*

Structural development in the young infant under normal conditions proceeds at a rate quite peculiar to this period of life The structure of nerve brain bone, and muscle depends entirely on the character of the food supplied during this period What is done then cannot be undone We cannot jerry build without suffering from the results

In the early part of 1903 the Infants Hospital was established in Denning road Hampstead The result of the work there has only been to convince me more and more of the vital importance to t
sent situation
site as soon as p
it is considered necessary that it shall be large enough to be organised on a proper basis and fitted with every arrangement for the saving of infant life and the furtherance of *scientific knowledge pertaining to this end For we need at* least one institution where the study of the many important problems involved can be systematically prosecuted This year the Infants Health Society has been established in the attempt to grapple with that great part of the problem not primarily belonging to the hospital—the prevention of disease and the securing for every infant food adequate in quantity and *quality* for his physiological needs I firmly believe that the present conditions of infant life most seriously threaten the welfare of the country And I am equally convinced that the remedy is comparatively easy if the importance of the issues is realised and due attention is given to the technical matters necessarily involved in providing a substitute for that most delicately constructed food—human milk

I am, Sirs, yours faithfully,

Harley street W July 9th 1904 RALPH VINCENT

ELECTRIC-LIGHT BATHS FOR HOSPITALS

To the Editors of THE LANCET

SIRS—I have been for some time contemplating the idea of making an urgent appeal to the authorities to introduce electric light baths into our hospitals for the use of both out patients and in patients We are in this matter far behind our German *confreres* as a visit last year to many hospitals in several German towns convinced me At these institutions for the treatment of poor people an electric light bath is a very usual part of the therapeutic outfit

Personal experience of this treatment in cases of rheu*matism myalgia* &c induces me to assert that recovery or improvement would take place much sooner under its employment than under the mere drug treatment of the present day Moreover the electric water bath is already in vogue at some of our hospitals, why should not the equally potent light bath be introduced? Surely in these days when the so called physical remedies are so largely employed our hospital patients should have the benefit of this particular mode of treatment and one which our private patients and the public generally are already using to such a large extent

I would also strongly advocate a trial at all events of the light baths in our fever hospitals for all cases when the rash is "suppressed" when we think of the power that this treatment possesses of filling the whole superficial area of the skin with blood surely it could not fail quickly to bring out the rash, in fact, under this treatment death from "suppressed scarlet fever," "suppressed small-pox," &c., should be things of the past. In the latter class of case, of course, the bath constructed for the reclining position would be the one chosen; the patient is as easily lifted on to this as on to a low couch, superficial suffusion would speedily ensue together with gentle perspiration, and the object in view would be rapidly attained.

Naturally, those of us who give this treatment can only take ordinary cases, therefore as regards results in fever cases I can but speak theoretically. The whole subject seems to me an important one and will, I trust, receive the attention of the profession generally.

I am, Sirs, yours faithfully,
J. STENSON HOOKER, M.D. Durh.

Gloucester-place, W., July 7th, 1904.

ACCIDENTAL REVACCINATION.

To the Editors of THE LANCET.

SIRS,—In reference to Mr. W. H. Bowen's case as reported in THE LANCET of July 2nd, p. 20, a patient sent a message for me stating that he was suffering from blood poisoning. My assistant saw him and prescribed, but as he became worse I called to see him and found a large vesicle on the under surface of the upper lip. He told me that some days earlier on arriving home from work he found that the public vaccinator had called and had put four spots on his child's arm. Being angry at the vaccination he sucked the spots. The child's arm "took" in spite of the heroic treatment, and the man was properly revaccinated.

I am, Sirs, yours faithfully,
Upper Pontnewydd, July 9th, 1904. ALFRED W. HAYLES.

MARGARINE FOR BUTTER.

To the Editors of THE LANCET.

SIRS,—It appears from your annotation in THE LANCET of June 25th that it is only recently that the fraudulent substitution of margarine for butter in "bread-and-butter" has been detected. On reference to the books of the late Camberwell vestry I find that there was a conviction for this offence first obtained by one of its sanitary inspectors in August, 1892, with others at intervals up to the present date; in each case fines varying from £2 to £1 were inflicted by the magistrate.—I am, Sirs, yours faithfully,

FRANCIS STEVENS,
Medical Officer of Health to the Borough of Camberwell.
July 6th, 1904.

SUPPRESSION OF URINE FOR NINE DAYS; OPERATION; RECOVERY.

To the Editors of THE LANCET.

SIRS,—The following case will be of general interest and should be placed on record. At 3 A.M. on March 21st last I was asked to see a patient, a stout woman, married, aged 48 years, who was suffering from acute pain in the abdomen. She had been uneasy on March 20th all the day but the excruciating pain, the most severe she had ever had, did not commence until after she had gone to bed and it then occurred in paroxysms. There was no abdominal swelling. During the previous five years she had had five attacks of similar, but less severe, pain and had passed in all five small calculi by the urethra. Three of these attacks of pain had taken place during the last six weeks. The only other illness she has ever had was a chill, accompanied by pain in her left groin, five years ago, which necessitated her remaining in bed for three weeks. With regard to her present condition, the pain in the abdomen being intense I gave her a subcutaneous injection of morphia at once and prescribed five grains of calomel to relieve her constipation.

As I was washing my hands previous to leaving I was informed, quite casually, that no urine had been passed since the previous Thursday, March 17th, at which I smiled from incredulity and said that probably some had passed when her bowels had acted, without her knowledge. But it instantly flashed across my mind, has she been suffering from acute retroversion of the uterus, with retention of urine, during the last six weeks which accounted for her three attacks of pain and not from ureteral calculus? I therefore renewed my examination, and, finding all normal in the pelvis, passed a catheter without drawing off one drop of urine. I visited her again on March 21st at 8.30 A.M., found her free from pain, and was shown the action of the bowels, resulting from the dose of calomel, which was entirely free from urine. I thereupon recommended her removal to the hospital for the purpose of investigation and possibly urgent operation.

I need not occupy your space with all the arguments and conjectures that arose on account of her anuria during the succeeding days, involving the questions of retention somewhere internally or suppression with the possibility of the supervention of uræmia. Physical examination from day to day revealed nc [illegible] rise of temperature. As she appeared in [illegible] was allowed ordinary diet, but with a restriction of fluid (she was satisfied with three ounces a day) on the theory that her urine must be accumulating internally and would have to be dealt with as soon as any indication arose. She was kept in bed and she had hot baths night and morning, which she could bear at 114° F., in the hope that they would facilitate the passage of a ureteral calculus; if, on the other hand, there was suppression of urine I hoped to afford relief by thus acting on the skin and on the bowels by salines. As she had previously passed successfully through similar, but slighter, attacks of pain, though without any interference with the urine, it was clear that we could only await the issue of events. Suffice it to say, that she was day by day carefully examined and critically watched and beyond the slight rise in temperature already referred to (morning 99°, evening occasionally 101°) there was no symptom of discomfort or ill-health of any sort or kind, not even a headache.

Now from Monday, March 21st, to Saturday, March 26th, not one drop of urine was passed, with or without catheter, although under the closest observation, and we have testimony which can be trusted, as I know the patient and her husband, that none was passed from 3.30 P.M. on March 17th until the close of the operation at 6.30 P.M. on March 26th, a period of 219 hours. On March 26th, when her evening temperature was taken at 5 P.M. it was noticed that she looked hot and flushed and the thermometer recorded 108°. I immediately received a telephone message of the fact and directed that both my colleagues, Dr. H. Simpson and Mr. W. A. E. Waller, should be summoned, whose advice and assistance I gratefully acknowledge, and at 5.30 P.M. she was placed under an anæsthetic. There being no indication as to the course to be pursued, after another examination while under the anæsthetic and the use of the catheter without result, I resolved to open the abdomen *and investigate inside.*

I made a four-inch incision through at least one and a half inches of subcutaneous fat in the abdominal wall, between the umbilicus and the pubes. I found the bladder empty; the ureters were normal in size; there was no distension of the pelvis of either kidney; both kidneys were slightly larger than normal as far as one could tell with the hand, and the right, apparently, was a little larger than the left. I then closed the abdominal wound; turned her well over on her left side; made an incision in the right lumbar region; and failing to feel a stone in the pelvis of the kidney incised the capsule over the convex border of the right kidney and cut through the structure of the kidney towards its pelvis. As, however, the hæmorrhage was rather free I resorted to both forefingers and very gently split the remainder until I reached the pelvis and thus saved much hæmorrhage. In the pelvis of the kidney I came upon about a drachm of rather strong-smelling concentrated urine and a small loose calculus which, in the great depth of the wound, I lost and never recovered. Deeply imbedded in the ureter at its junction with the pelvis of the kidney was an apparently branched stone, which, do what I would short of splitting the ureter (with every kind of instrument), I was unable to move. I therefore left it *in situ* believing that when the congestion of the kidney was lessened the kidney would diminish in size and the stone be less gripped by its pelvic tissues. I packed the wound with iodoform gauze and dressed it with wood wool. During the night the urine drained freely from the wound into the wood wool and owing to the relief of tension 12 ounces of blood-stained urine were passed naturally at one time. She progressed uniformly well without a single drawback, passing urine both by the wound and from the bladder every day. She was given ten grains of salol three times a day, which kept the urine sweet and the wound from irritation. Subsequently urotropine was substituted as the urine became alkaline. Instead of dressing the wound with wood wool I placed under her loins, cross-wise, an indiarubber bed pan, with air-water rim, which collected the draining urine and saved her from becoming wet On April 8th, I determined to make another attempt to secure the calculus and although it was gripped less tightly I had the greatest difficulty in extracting it on account of its shape and its depth in the ureter, but I was eventually successful It was pyramidal in shape, somewhat resembling a cocked hat, flat, with an excrescence at one end which became detached (this was mislaid by the nurse) The part that filled the ureter and completely "corked" it weighs 32 grains On May 28th she was able to be up, a few days later she walked about, and on July 5th she left the hospital in good health but the urine still issuing from the wound in diminishing quantity.

The case is remarkable in that suppression of urine resulted instead of distension of the pelvis of the kidney There can be no doubt that the secretion of an organ may be arrested by inhibitory nervous action But how was it the left kidney failed to secrete urine? Is there a similar stone there? Or can a stone in one ureter inhibit the action of both kidneys? I have seen total suppression of urine and death occur from passing a sound for the relief of stricture of the urethra Also how was it that there was no uræmia when suppression of urine lasted for 219 hours? The sudden rise of temperature to 108° probably signified its advent, which was however, forestalled by immediate operation It would occupy too much of your valuable space to discuss these questions in their entirety I must be content with recording the facts

Rugby, July 7th, 1904 CLEMENT DUKES

THE TREATMENT OF HÆMORRHOIDS AND ALLIED CONDITIONS BY OSCILLATORY CURRENTS OF HIGH TENSION

To the Editors of THE LANCET

SIRS,—In his paper on this subject in THE LANCET of *July 2nd*, p 19, *Mr T J Bokenham makes the statement* that the results of the treatment of hæmorrhoids and other minor troubles of the anus and rectum by high frequency currents are "far superior to those obtained by any other local treatment short of operation" Judging from the results given in his paper I do not think that any surgeon who has had much experience of rectal surgery will agree with this statement and I do not think it is one which should be allowed to pass unchallenged It is a well known fact that minor degrees of hæmorrhoids can often be cured by slightly stretching the sphincters by the occasional passage of bougies and I think the beneficial results obtained by the electrical method described were quite as much due to the slight stretching of the sphincters by the passage of the electrode as to the effects of the high frequency current

The treatment of "acute or recent capillary piles" by slightly stretching the sphincters combined with the application of suitable astringents and regulation of the bowels is the ordinary treatment in use at St Mark's Hospital and it certainly gives much better results than 14 cures in 25 cases, which is the percentage of cures claimed for the electrical treatment, and this without any of the risks of electrical or x ray burns which Mr Bokenham admits exist in the treatment by high-frequency currents and which in less experienced hands than his might result in serious damage to the patient So that, so far as hæmorrhoids are concerned, there does not appear to be any advantage in the treatment by high frequency currents, but rather the reverse

With regard to the treatment of simple fissure the electrical treatment certainly seems to have no advantage over the ordinary non operative methods The large majority of the cases of simple fissure which come to the out patient department at St Mark's Hospital are treated by local applications and are cured in from three to four sittings or even less and this without causing pain or preventing the patients from continuing their ordinary occupations One would have supposed that the passage of a large electrode into the rectum caused intense pain in cases of fissure, as such patients cannot usually even tolerate an examining finger.

I am, Sirs, your faithfully,

Cavendish-place, July 4th, 1904 P LOCKHART MUMMERY

INTRABRONCHIAL INJECTIONS IN PULMONARY DISEASES

To the Editors of THE LANCET

SIRS,—As I have largely devoted myself for many years to the development of the treatment of phthisis by direct injections, perhaps I may be allowed to make a few observations on Professor Paul Jacob's communication, referred to by your Berlin correspondent in THE LANCET of July 2nd? With his premisses—'the treatment of tuberculosis by medicine had hitherto failed because of the impossibility [?] of bringing a sufficient quantity of any drug into contact with the diseased parts by ordinary methods of internal administration"—everyone must agree I recognised it 13 years ago *and stated the matter three years later as follows* "To bring the remedial agent into direct contact with the diseased part is a principle so well recognised in surgery that it should require no argument to prove the rationale of extending its application to diseases of the respiratory system "[1]

Having tardily recognised a truism, Professor Jacob appears to have repeated a number of experiments on animals which were reported nearly 20 years ago—to prove the absorbent power of the lungs and that intrapulmonary injections could be performed "without any symptoms of suffocation ' The *Practitioner*, vol xxxvi, *1886*, reports similar experiments performed by Schrward and Reichert, and Professor Sterling recently informed me that it had been demonstrated years ago that a horse's lungs would readily absorb six litres of fluid It would appear, therefore, that in his preliminary observations and experiments Professor Jacob is somewhat belated The difficulty of placing fluids [illegible] bifurcation" of the bronchus [illegible] I said "If when the injec[illegible]be directed *to incline* or lie on [illegible] that the bulk of the fluid will gravitate in the desired direction"[2] This, however, was insufficient and I now use a revolving chair[3] which Dr William Ewart thinks ' has solved the problem ' Cocainisation is quite unnecessary

Passing the question of the particular drug to be injected *I come to Professor Jacob's difficulties* which, *from the Deutsche Medicinische Wochenschrift* of June 23rd, are, I gather, as follows first, as in inhalations the bulk is absorbed by the upper air passages, and secondly, a large quantity of the injected solution is coughed up immediately after the injection Well I wish to speak with great respect, but Professor Jacob has treated five human beings—I have treated nearly 200—and as I inject over *one hundredweight* of fluid a year I think I know, and am in a position to demonstrate, that he is in error

I am, Sirs, yours faithfully,

Southport, July 12th, 1904 COLIN CAMPBELL

ROYAL ACCOUCHEMENTS

To the Editors of THE LANCET

SIRS —Dr W Williams in his valuable lectures on Deaths in Childbed, states in THE LANCET of July 9th, p 65, as follows "The death of Princess Charlotte of Wales and her unborn son, a death which led to the ascent of the late Queen Victoria to the throne, did much to accentuate this progress [that of men midwives in public favour] and for the first time in our history a Queen of England was attended in her confinement by a man ' In the interests of historical accuracy may I point out that Queen Charlotte Sophia, the consort of George III, was attended by the celebrated Dr William Hunter It is true that, in accordance with the custom of those days, Dr Hunter waited in an anteroom to give his assistance if and when it was needed by the midwife He was first called to attend the Queen in 1762 when he informed the King, so it is related, that she was "with bairn" An autograph diary of his attendance upon Her Majesty, including three confinements, is preserved in the Hunterian Museum in Glasgow From the birth of Queen Charlotte's youngest child in 1783 there was no strictly royal birth in England until that of Queen Victoria's eldest child in 1840 In the meantime obstetric physicians had attained to an honourable status and I question whether the term "man midwife" was applied to the leaders in the art much after the middle of the eighteenth century. William Hunter himself, although Horace Walpole calls him in banter "that Scotch nightman," was an M.D., F.R.S., and Foreign Associate of the French Academy, being in fact one of the foremost men in the medical profession in England in his century (see the writer's memoir, "William Hunter, Anatomist, Physician, Obstetrician"). As regards the Princess Charlotte of Wales it is commonly said that her death in 1817 occurred *after giving birth* to a still-born male child.

THE PASSING AWAY OF THE ALL-ROUND INTELLECTUAL GIANT.

To the Editors of THE LANCET.

SIRS,—Time was when the pursuit of scientific research might have been likened to the unravelling of a rope into its strands, whereas now the life of a man seems not long enough to devote special and complete study even to a single strand. The enormous acquisition of facts and the prospect of so many possibilities and probabilities opened up day by day overwhelm the mental and physical capacity of a single individual who therefore finds that he is compelled to resign so much of the task of research to others, confining to himself an apparently small field in which to labour but in which enough material appears for a life-long exploration. The possibility of gaining a general knowledge of natural science grows more remote as revelations are made. Innumerable paths of study are opened up in which, if revelation is to be anything like complete, it is impossible for all to walk. In a word, specialism is compelled upon those who would wrest from Nature her secrets and who would make an attempt to formulate her designs. There is no limitation to study in any given subject. No man will ever be able to sit down and say with a particle of truth, "I have finished the task which at the beginning was placed before me," even though he has "specialised." "Specialising" must eventually lead to the extinction of the "all-round" intellectual giant but the great danger of special study is that the scientific *tout ensemble* may be lost sight of and an inability to comprehend the grand scheme may blight our chances of ever throwing a light on life's great problems. The pieces may be found but who shall fit them in their proper place so that an intelligible whole may be presented? An expert in one subject is very often completely unintelligible to an expert in another subject. Both are engaged in a study of natural phenomena but their individual findings may have no apparent relation to each other. Even in the same denominational class of study one man deviates into a branch of the subject and another man into another and each possesses a special knowledge which cannot be shared. Thus, to take but one example, there are the technical chemist, the "pure" chemist, the analytical chemist, and the pharmaceutical chemist, all well grounded in the principles of that section of science which each has studied, each pursuing a perfectly separate and distinct line and each practically ignorant of the others' gain of knowledge. What chance, again, have such men of gaining any exact knowledge of, let me say, physics or astronomy? The old familiar adage "Jack of all trades, master of none" appears in a new light and its sentiment is very keenly realised in the pursuit of scientific knowledge and in those professions in which such knowledge is indispensable. Giant intellects there are amongst us but owing to the enormous growth of detailed knowledge the "all-round" man must become as extinct as the dodo. The man who thought that he possessed a general knowledge 20 years ago realises with Newton that he has been only like a boy playing on the sea-shore diverting himself in now and then finding a smoother pebble or a prettier shell than ordinary, while the great ocean of truth lay all undiscovered before him. Instances arise now and then of giant intellects comprehending the whole domain of physical science. Such a one was the late Sir George Gabriel Stokes, to whom recently and most deservedly a memorial was placed in our national shrine by the side of those of Newton, Herschel, Darwin, Adams, and Joule, but such instances must necessarily diminish as knowledge spreads.

I am, Sirs, yours faithfully,

July 12th, 1904. CHEMICUS.

CHOLERA IN MESOPOTAMIA AND PERSIA.

(FROM THE BRITISH DELEGATE TO THE OTTOMAN BOARD OF HEALTH.)

DURING the past two weeks there has been a diminution of the cholera outbreak in Turkish territory, but an extension of the disease in Persia. Its presence has also been reported from places on both shores of the Persian Gulf.

The following returns from Basra are in continuation of the figures given in my last letter[1]:—

From June 4th to June 11th ...	14 cases and	11 deaths.
,, ,, 12th ,, ,, 18th ...	10 ,,	5 ,,
,, ,, 19th ,, ,, 25th ...	4 ,,	3 ,,
,, ,, 26th ,, July 2nd ...	4 ,,	4 ,,

The outbreak in the Basra lazaret is now at an end. Between May 29th and June 3rd 25 cases and 15 deaths occurred here; in the following week the figures dropped to 12 cases and 8 deaths; there was a single death on the 12th; and finally, on June 21st the husband of a patient already convalescent was attacked by cholera and died. Active measures are in progress for the removal of the lazaret from its present position to a more convenient site on the eastern bank of the river, opposite to the town of Basra.

At Bagdad cholera reappeared on June 4th after an interval of just two months, during which the city was believed to be free from the disease. The following figures have since been reported:—

From June 4th to June 6th ...	? cases ...	4 deaths.
,, ,, 8th ,, ,, 11th ...	9 ,, ...	8 ,,
,, ,, 15th ,, ,, 22nd ...	5 ,, ...	2 ,,
,, ,, 23rd ,, July 3rd ...	9 ,, ...	7 ,,

It is probable that these figures are below the truth. On June 21st a case of cholera, which proved fatal next day, developed on board the English gunboat stationed in the Tigris. The ship was consequently removed some distance below Bagdad where she underwent ten days' isolation, thorough disinfection, and repainting.

The outbreak in the Shiah city of Nedjef, the commencement of which was reported in my last letter, proved to be a severe one. After the single cases there on May 24th and 31st a few more cases occurred in the first week of June. But on the 9th of that month the disease became suddenly epidemic, as shown by the following figures:—

On June 9th and 10th	155 cases ...	93 deaths.
From June 11th to June 18th...	260 ,, ...	297 ,,
,, ,, 19th ,, ,, 24th...	67 ,, ...	75 ,,
,, ,, 25th ,, ,, 29th...	18 ,, ...	13 ,,

In the other holy city of the Shiahs, Kerbela, the epidemic began rather later, apparently about June 14th. The following are the subsequent returns from Kerbela:—

From June 14th to June 17th...	3 cases ...	2 deaths.
,, ,, 18th ,, ,, 24th...	122 ,, ...	207 ,,
,, ,, 25th ,, July 1st ...	27 ,, ...	177 ,,

The majority of fatal cases here were only discovered after death had occurred.

A severe outbreak of the disease has also occurred at Hilleh, on the Euphrates, in the marshy district between the two Shiah cities just mentioned. For the past two or three weeks, indeed, the centre of intensity of the cholera epidemic has been in this neighbourhood. The following are the returns for Hilleh:—

From June 6th to June 8th...	5 cases ...	2 deaths.
,, ,, 9th ,, ,, 14th...	116 ,, ...	87 ,,
,, ,, 15th ,, ,, 24th...	143 ,, ...	197 ,,
,, ,, 25th ,, ,, 30th...	18 ,, ...	36 ,,

Smaller figures have been reported from a large number of other places in the Hilleh district. Elsewhere, with the exception of certain tribes in the Montefik district, the reported cholera mortality has been considerably less. But until the past week the infection was present in most of the places mentioned in my former letters and in some others not mentioned there. But fortunately in most the epidemic is now a declining one and the total number of cases and deaths reported from all places within Turkish territory fell from 481 and 852 respectively in the week ending June 28th to 210 and 355 respectively in the week ending July 4th.

---

[1] THE LANCET, June 25th, p. 1812.

It may be hoped, therefore, that the worst of the epidemic is over on this side of the Persian frontier. But the disease is spreading in Persia and the danger of its passing up to Transcaspia and the Caucasus and so threatening Europe is one that cannot be ignored.

At Khanikin, the Turkish frontier town, only a small number of cases have been officially reported. At Kermanshah, in Persia, the following figures have been returned since the date of my last letter:—

From June 1st to June 8th ... 39 deaths.
" " 9th " " 15th ... 13 "
" " 16th " " 21st ... 59 "
(and as many cases).
" " 22nd " " 29th ... 49 deaths.

These figures indicate a slight recrudescence of the disease in the second half of June. On the 17th it was announced that cholera had appeared at Koum, a town of importance 24 hours' distance from Teheran, and also in the neighbourhood of Bushire on the Persian Gulf. On July 5th a telegram from Russian sources was published in the newspapers stating that 150 deaths from cholera were occurring daily in Teheran itself. The Turkish sanitary administration has received no confirmation of this announcement. But the fact that cholera is present in the Persian capital is reported, and last week the Ottoman delegate on the Teheran sanitary board was himself attacked by the disease and died after a short illness.

No further news has been received of the reported outbreak of cholera at Bushire but on July 1st the disease was stated to have appeared at Mohamera, the Persian port on the Shatt-el-Arab, a short distance below Basra.

Finally, it has to be added that cholera was reported to have broken out in the Bahrein Islands, near the southern end of the Persian Gulf, in the middle of May; that on June 20th the presence of the disease was reported from two villages (Darein and Narvet) in the district of Katif, on the western shores of the Gulf; that on June 28th a telegram from Basra announced that cholera had been present for a month in Katar (the district south of Katif) and had just appeared in Katif itself and at Dekin (a name I am unable to identify); and that about the same time a few cases of cholera occurred at Muscat and in two villages opposite to this port.

Constantinople, July 8th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Parsi Maternity Hospital in Bombay.—A New Water-supply for Mussoorie.—The Decline of the Plague Epidemic.—Increase of Enteric Fever at Lahore.—The Health of Bombay City.

THE Parsi Maternity Hospital in Bombay has proved a valuable boon to the community and has gained so highly in popular favour that during the past year very nearly half the number of Parsi children born in the city had their birth in this institution—viz., 529 out of 1168. Some 15 or 20 [illegible] responsible for it. The hospital was started and has continued to progress ever since. The death-rate of women in the hospital does not come to even ½ per cent., while outside the hospital the death-rate amongst Parsi women is 3 per cent. It is a curious fact that there have always been more births in the institution from July to December than in the first half of the year, but for this there is no explanation. The same proportion of births during the first half and the second half of the year holds true in the case of births outside the hospital. Nearly 20 per cent. of the women admitted were treated and fed free of charge. The patients come not only from the city but from all parts of the provinces and even from distant parts of the country. The hospital saves the lives of children as well as of mothers because it is found that the death-rate among children born outside the hospital is almost double the death-rate in the hospital. Being con- [illegible] it is an [illegible] supply at Simla other hill stations are moving in this direction. At Mussoorie the Kimpti Falls are to be made use of and a scheme for electric lighting also by utilising these falls is under consideration. The main reservoir is to be on Blucher's Hill, several hundred feet above the town. From the main reservoir a pipe-line is proposed to be run to the top of Vincent's Hill and another to Camel's Back Hill, the water-supply of Landour being treated separately. The available quantity of water from the springs is given at about 10,000 gallons per hour and the quantity to be pumped will provide water at the rate of 11½ gallons per head. Distribution will be by means of pressure tanks spread over the area with hydrants and also house-to-house supply if required.

The plague epidemic is rapidly on the wane, only 7762 deaths being reported for the whole of India during the week ending June 11th as compared with 13,770 for the previous seven days. The distribution of the mortality is as follows: Punjab, 6491 deaths, as against 12,219 the week previously; Bombay districts, 416, as against 547; Kashmir, [illegible] 165; United [illegible] against 129; [illegible] 71; Karachi, [illegible] is danger of a [illegible] aving already been reported

I *regret to hear of a considerable increase of enteric* fever in the Lahore district during the past few months necessitating the issue of special orders particularly with regard to preventing the spread of the disease by men who are convalescent from it.

The report of the health officer of Bombay for the first quarter of 1904 shows a remarkable improvement on the mortality figures as compared with all the corresponding quarters since 1896 There were 7524 deaths from plague which was almost the only factor in the increase over the normal mortality. The returns have for the last year or two been more satisfactory, inasmuch as the plague returns practically account for the increased mortality, whereas previously the increase was unexplained. The diminished plague mortality may be due to the measures taken, including evacuation, or to an acquired immunity of the people. The health officer asks for a great deal, however, when he says: "If we can evacuate the infected houses, remove all insanitary and plague-stricken areas, provide the people with suitable dwellings, open up insanitary areas, and continue to enforce sanitary measures, we can curtail the course of the disease to controllable limits." If dependence is placed on such Utopian ideals the plague is likely to last some time in Bombay. Overcrowding is the great evil in Bombay city, by which is meant that the number of persons and animals collected together in a certain space, room, or area, workshop, factory, hospital, tent, hut, &c, is so great that it vitiates the air, diminishes vitality, and death and disease result. The health officer complains that the overcrowding has been accentuated by the displacement of many people by the Improvement Trust schemes, that this displaced population has not yet been provided for, and that there are urgent want and demand for cheap dwellings for the poor.

June 24th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

University Matters.

[illegible] been approved for the [illegible] fect after the issue of [illegible] or the degree will have to present a thesis embodying observations in one of the following subjects: (*a*) [illegible] anatomy; (*b*) physiolog[illegible] logy; (*d*) bacteriology; [illegible] (*g*) medicine; (*h*) menta[illegible] or public health; (*j*) toxicology; (*k*) legal medicine; and (*l*) midwifery. In addition to this the candidate will be required to pass a general examination in the principles and practice of medicine but it will be in the power of the board of examiners to exempt a candidate whose thesis is of exceptional merit from any part of these examinations. The council has decided to constitute a new grade amongst the members of the junior staff—that of special lecturer. The appointments will be of a personal nature and *will not be attached to any department* or subject, but will be made on account of special distinction gained in any branch of the department by any lecturer. The special lecturers will have to take their ordinary share in the work of their departments under the direction of their professors. Two of the first appointed special lecturers belong to the medical faculty—viz., Mr. William Wright, special lecturer on osteology, and Dr. James Miller, special lecturer on bacteriology. At the recent Congregation for the conferring of degrees each of these gentlemen received the degree of doctor of science, which was conferred upon them in respect of theses submitted for the purpose. Dr. James Kerr, medical officer to the late School Board of London, and now the occupant of the same position under the education authority of the London County Council, has been appointed Ingleby lecturer for the year 1905 and will give two lectures during that year on feeble-minded children. Dr. John H. Watson has been appointed second demonstrator of anatomy. The many friends of Professor Gilbert Barling have seen with great pleasure that he heads the list of those elected to fill positions on the Council of the Royal College of Surgeons of England.

Health of Birmingham.

The report of Dr. A. Hill (who held office up to the end of last September) and of Dr. John Robertson (who then succeeded him) on the health of the city for the year 1903 has recently been issued. It states that the year was a remarkable one from the point of view of its healthiness. The death-rate continued low during the whole of the year and "we have now the satisfaction to record that the annual mortality rate was the lowest on record. Indeed, it is probable that the rate during last year was lower than in any year since Birmingham emerged in the distant past from the condition of a village into that of a small town. The mortality-rate was 17·2 per 1000 last year, against 18 in the previous year and 20 in the previous ten years." It is pointed out that this favourable position was largely due to the weather which, by keeping the temperature at a mean, produced a favourable bill of health. The report continues, "It is possible, however, with reasonable cleanliness in our houses, in our food supplies, and in our general surroundings, that warm weather shall not have the same disastrous effects as it has had in past years, and that improved moral and physical qualities resulting from better education and increased prosperity, individual and general, will confer the means of securing greater protection from the dangerous and fatal rigours of the winter season. If we consider the progress made in the health of the city during the 30 years commencing with 1874, when the death-rate was 26·8, and ending with 1903, when the death-rate stood at 17·2, a diminution of 40 per cent., we feel justified in the anticipation that very great benefits are in store for our race in the future." The city contained 111,309 occupied houses, an increase on the 1896 figures of 10,452. The marriages registered in the city were 4881, a rate of 18·4 per 1000. The births were 16,866, or 31·7 per 1000. Only once since 1873 was the birth-rate lower and that was in 1894. The rate for that year was 31·6. The infantile mortality rate was 158 per 1000 births and in this Birmingham has an unenviable prominence, relatively speaking. The serious epidemics during the year were of scarlet fever, though the number of cases was not so high as in 1902, and of diphtheria, of which there was a larger number of cases than in any year since 1896. Out of 251 cases of small-pox there were only 12 deaths. There were 1025 deaths from tuberculous disease and the medical officer recommends the adoption of a system of voluntary notification. He adds that there are in Birmingham at any one time, probably at least 3000 cases of phthisis and alludes to the possible necessity of a corporation sanatorium. The officers of the department represented 304 houses as unfit for habitation during the year. 65 closing orders were obtained, 51 notices of demolition were served, and 34 houses were demolished. In connexion with the milk question the report says: "It is very important that effective and uniform action should be taken in the matter of supervising cowsheds outside the city, from which part of the city milk-supply is drawn. In these rural districts milk is produced under filthy conditions in a good many instances and sent into the city. In summer time such milk is probably one of the means of setting up epidemic diarrhœa among young children." The assistant medical officer of health is at present making an inspection of every milk-shop in the city with a view to drafting some general regulations in regard to their conduct, as it is found that contamination of the supply is probable from the conditions in which the milk is kept in some of these shops. The inspectors condemned during the year 223 tons of bad meat, 93 tons of bad fish, and 17 tons of bad fruit. The 639 city bakehouses include 41 underground, and of these 22 have been voluntarily closed. 14 others have been certified as fit, four were refused certificates, and one case was pending when the report was written. The health visitors made 26,170 visits during the year and the table relating to their work shows that 3935 tenants were advised to open windows, 1109 to get rid of lodgers, 335 to wash their children, and 622 to feed their infants properly.

Small-pox in the District.

Another case of small-pox has been reported to the Birmingham medical officer of health in the person of a man who came from Worcester in an infectious condition, the symptoms of the disease becoming apparent a few days later. The man was removed to the hospital, the house was disinfected, and those who had been known to be in contact with him were placed under inspection. In Worcester there has been an outbreak originating in an inmate of the casual ward of the workhouse. The case was of a mild character. Another inmate of the same ward, who had come there from one of the lodging-houses in the city, has also been discovered to be suffering from the same disease. A malignant case of small-pox has been discovered in the Cannock Chase district, in the person of a man, a native of Stafford, who applied for admission to the Cannock workhouse early one morning, stating that he had been wandering about all night. As it was clear that he was suffering from small-pox the master of the workhouse refused him admittance and he was taken into the small-pox hospital. Previously to coming to Cannock he had slept at a lodging-house in Rugeley. Dr. J. G. Beasley, medical officer of health to the Rowley district council, reported to his authority that a female small-pox patient had escaped from the isolation hospital under the control of the South Staffordshire Joint Small-pox Hospital Board and was, after some days' lapse of time, still at large. The police and workhouse officials for a distance of ten miles round the district had been communicated with but no trace of the woman could be found.

July 12th.

MANCHESTER.

(From our own Correspondent.)

Mersey and Irwell Watershed.

It really seems as if the Mersey and Irwell joint committee was beginning to make some progress and that its efforts for the purification of the rivers and streams of the watershed were not in vain. On July 5th a report was presented by Mr. R. A. Tatton, the chief inspector, which was on the whole encouraging. In commenting on the report, Sir J. T. Hibbert said that the watershed included 95 authorities and had a population of 2,502,000 persons. There are five important rivers in its area, of which the Irwell and the Rouch have 286 manufactories on their banks; the Irk, in old days a noted trout stream, 45; the Medlock, 15; and the Mersey, 98. One serious form of pollution with solid matter, he said, was now a thing of the past, but a few years ago all the cinders and other solid rubbish from the various works were tipped into the streams or placed where the winter floods would wash them from the banks, for the readiest way of getting rid of a nuisance was to pass it on to the neighbour lower down and the gradual silting up of the river-bed was a matter with which the manufacturers did not concern themselves. The sludging of the mill lodges, as the reservoirs for the works are called, was for many years a serious difficulty, but that has been overcome. Serious pollution, however, still takes place when condensing lodges, in which polluted water is used, are run off. Mr. Tatton "mentioned the difficulty that existed with the stone polishing industry," but the solid matter from that source is now intercepted. 12 years ago there were 27 sewage works in urban districts, now there are 86, and ten in rural districts. Now there are only two urban districts without sewage works and both have schemes in hand. In 1891 there were 191 works without any system of dealing with their effluent; now there are only five. 278 manufacturers have now efficient purification plant, as against 45 in 1893. No doubt each of the various industrial processes has its own difficulties Of 120 dye works 88 have efficient plants, of 75 bleach works are 56 efficient, of 59 woollen works 44, and of 48 print works 38, while only three out of 12 breweries can claim efficiency The rivers are now so much less filthy than they were that the water is becoming more useful for manufacturing purposes Sir John Hibbert is not very sanguine, for he says they can never expect to make the rivers attractive, but 'they could make the water of commercial service and they could do much for the health of the people living on the river banks" This is a somewhat melancholy conclusion to come to, for these streams have even yet traces of beauty in quiet reaches, swirling pools, and rippling shallows the sight of which makes one feel that man should be ashamed to foul everything which he touches There is said to be "much less decomposition going on in the water of the Ship Canal than formerly, and the formation of gases is nothing like what it once used to be" Let us hope that there will be still further improvement for it is impossible to imagine, and one would think to endure, anything more malodorous than the summer fragrance of the Ship Canal Sir Henry Roscoe agreed in the main with Mr Tatton's report and spoke of the difficulties connected with special trades as, e g, that of the fellmongers, 'owing to the noxious character of the effluent' As to the progress made in the application of scientific methods of filtration he said that in 1898 there were only six and a half acres of artificial filter beds in use in the watershed There were now 105 acres while the area for land filtration had only increased from 913 to 1151 acres The volume of sewage to be filtered at 75 gallons per head of the population, amounted to 187,500 000 gallons a day To carry out artificial filtration at the rate of 250 000 gallons per acre, which gives 'a satisfactory effluent within the limits of impurity allowable, would require seven and a half times the present area, or 750 acres, which he thought we might look forward to Land filtration would require some 10 000 acres, which would be out of the question Manchester possesses half the total area of artificial filters at work in the watershed but they are not sufficient, and the rivers committee is making 'praiseworthy efforts to complete its scheme As regards the general results, Sir Henry Roscoe said that "the water which previously was unfit for industrial purposes was now usable There seems to be no sufficient reason for being content with this partial purification of Lancashire rivers and although Sir Henry Roscoe speaks cautiously he says that much more remains to be done

University Students Congress

The first English and Welsh Inter Universities Students Congress, to give it its full title just held in Manchester has had an encouraging success Its objects were to

the students and to advance

The universities represented

Durham, Leeds Liverpool,

Wales, and St David's College, Lampeter, and the delegates numbered about 40 They were welcomed by Dr Alfred Hopkinson Vice Chancellor of the University of Manchester, who was able to say pleasant things all round He touched on three of the subjects down for discussion one being the provision of residential halls which he thought of 'enormous importance to university life He next spoke of the question of volunteer corps in connexion with the universities There was one in connexion with the University of Manchester and "he hoped the movement would grow and that it would be felt to be a desirable thing for members of a university to prepare themselves to take a part, if need be, in the national defence' Professor Schuster proposed a motion on 'The Reform of University Degree Courses,' which ran as follows —

on ;

This was passed after considerable discussion by 23 to 6 Professor Schuster in his reply said that the medical faculty stood on a different footing from the arts, and pointed out that as regarded the University of Manchester the practice on the medical side was very much what he advocated 'No classes were given in the examinations at all except for the M D degree, preparation for which was understood to consist of original work." Mr F T H Davies (Birmingham) proposed a motion in favour of an inter university volunteer corps In addition to its importance as regards national defence he spoke of it as tending to companionship and to the obliteration of the division between the faculties of arts and medicine Mr William Thorburn related the conditions under which the Owens College company of the 2nd Volunteer Battalion Manchester Regiment which he commanded until recently, came to be formed He regretted very much that he had to give up the command of the company, "but the way it had to be conducted in order that it might fit in with the general working of the battalion rendered it impossible for him and also for many of the students to carry on their work" He said that there were many students who would be glad to give a month to work in camp in association with a university battalion, and in that way "they would obtain a training which would be of the greatest value to them in after life in the army, in the Indian Medical service, and in other positions all over the world' He suggested the appointment of a committee to report to the congress next year and it was decided to form a committee of five There was a strong and apparently unanimous feeling in favour of the movement

Appointment and Awards at the Victoria University, Manchester

Dr A Hill Griffith has been appointed clinical lecturer in ophthalmology A Fellowship in sanitary chemistry has been awarded to Dr W B Ramsden The Dauntesy entrance medical scholarships were awarded to Marion Stocks and A E Woodall and the Dumville surgical prize to P Talbot Various awards were also made on the arts side

Scarlet Fever at Warrington

Scarlet fever has been very prevalent at Warrington In the first quarter of the year Dr J G Gornall the medical officer of health, has reported that 232 cases were returned The average number for the last ten years has been 37 Of the 205 cases removed to hospital eight died, or 3 9 per cent Dr Gornall has notified the head teachers of the elementary schools that discharged patients must not be readmitted to school till he has given a certificate that they are fit to return and this certificate he will not grant for some weeks in any case The chairman of the health committee commented severely on the action of the education committee in not acceding to the suggestions of Dr Gornall to close the schools immediately

July 12th

IRELAND

(FROM OUR OWN CORRESPONDENTS)

Coombe Hospital, Dublin

THE annual meeting of the supporters of the Coombe Lying in Hospital was held on July 6th, the Lord Mayor being in the chair When the report had been read Mr T G. Stevens, in moving its adoption, alluded to the great increase in the number of patients during the last 12 months and to the increase in the number of students attending the hospital. The Rev Dr Smyhe seconded the motion and said that the hospital had now risen to a high degree of eminence and usefulness The Lord Mayor in putting the motion, remarked that as an old member of the hospitals committee of the corporation he noted with pleasure the improvements that had been made in the buildings and promised that he would recommend his colleagues to give an increased grant to the institution

Apothecaries Hall of Ireland

The annual meeting and dinner of the Apothecaries Hall of Ireland were held on June 25th, Dr A Atock, the governor, being in the chair Sir Charles Cameron dwelt on the ancient foundation of the institution which dates from the year 1746 and to the charter of 1791 under which it now exists The governor mentioned that there were over 500 apothecaries on the present roll besides a large number of assistants and said that the diploma of the Hall not only qualified in pharmacy but also conferred the right to practise in medicine and surgery

Health of Belfast during 1903

The report (rather a belated one) of Dr H Whitaker, superintendent medical officer of health of the city of Belfast, for the year 1903, has just been issued in printed form. The total number of deaths from all causes has been less numerous (7169) than in any of the past six years, and the deaths from zymotic diseases (792) are also fewer, "a matter for thankfulness," considering that in each of the previous two years the deaths were over 1000. In 1903 there were 2902 cases of infectious disease notified, and attention is called in the report to the fact that this number is smaller, but I fear that the notification of disease is carried out (at least in comparison with any English city) in anything but a complete way. The number of typhoid fever cases notified was only one-third of those notified in 1901. Two of the most serious of the zymotic diseases are not notifiable—measles and whooping-cough—and were very prevalent during the year. There were 11,488 births in Belfast (the population of which is 349,180) in 1903 and 7169 deaths, showing a natural increase in the number of inhabitants of 4319. Of the total number of deaths (7169) during 1903, 792 were due to zymotic diseases and 2675 to chest affections, making a total number of 3467, or rather less than one-half of all the deaths registered as having occurred in Belfast. What is the cause of the deaths of the remaining 3702? It is deplorable to read in this report such a humiliating statement from the health officer as: "I regret that I have no information which would enable me to place before you the causes of death of the other 3702. In most of the other large centres of population the medical officer of health is supplied with this information and with us it could be obtained, as also the names of the streets and numbers of the houses in which the deaths occurred, by arrangement with the registrars of the respective districts. I know nothing of where any deaths take place except from the Registrar-General's returns, which merely state that so many deaths occur in a certain district. As these districts comprise hundreds of acres and thousands of persons, it is impossible for me, even approximately, to state where they occurred." Again, of the 2675 deaths from chest affections, 1030 were attributed to phthisis, while of the remaining 1645 deaths attributed to diseases of the respiratory organs Dr. Whitaker says: "I have no means of estimating the numbers of the different forms of chest affections." How can one criticise a report in which the medical officer of health of a great city like Belfast, with a population of nearly 350,000 people, calmly admits that he cannot get at the causes of the death of 3702 persons and that he is unable to differentiate under their proper heads 1645 cases of death from diseases of the respiratory organs? Truly the state of the science of public health in Belfast is embryonic. Speaking of phthisis it is a remarkable fact (surely needing some explanation) that while in Belfast during the year 1903 one out of every 348 inhabitants died from phthisis, it is said in this report that there were no deaths (p. 29) in the Forster Green Hospital for Consumption and Chest Diseases during that year. Of the deaths from zymotic diseases (792), 293 were from measles (125) and whooping-cough (168). Surely such statistics indicate that such maladies should be made notifiable, while some steps should be taken to prevent 277 deaths from diarrhœa (which is classified under the head zymotic diseases). On p. 5 a table is given showing the number of cases of infectious disease notified as having occurred in the several dispensary districts and nearly six pages are devoted to describing the boundaries and characteristics of these districts, which is absolutely useless, as without a map (which would occupy one page) it is impossible to follow such a description; while more than seven pages are filled with an account of the weather in the various months in relation to the prevailing diseases, and four pages have a list of streets in which typhoid fever occurred in 1903, which is really of no value. The total number of pages of the whole report is 54 and of these I think that those 17 which have been referred to might be entirely omitted as being quite unnecessary. This report is far from satisfactory; it gives the impression that the public health department in Belfast needs great reforming. The medical officer of health makes many most useful suggestions but apparently he gets little support from his committee. Matters are allowed to drift on in an aimless way, no new departure comes as a suggestion from the public health committee; everything needs to be forced on it from the outside; its new infectious diseases hospital will not be ready until Nov. 1st, 1905, and it has still to grapple with the consumption question. The policy of putting off all reforms only ends in disaster and now the citizens of Belfast will have to be taxed heavily for a number of things (infectious diseases hospital, tuberculosis sanatorium, main drainage, &c.) which should have been dealt with one by one and not altogether. In Belfast in public health affairs what is needed is someone who would really guide and direct the public health committee as to those necessary reforms which are pressing and which must be passed if the city is to maintain its high position.

Fermanagh County Infirmary.

Dr. L. Kidd, surgeon to the County Fermanagh Infirmary, has been granted an increase in his salary of £25 per annum. The sum of £119 15*s*. 6*d*., the result of public subscription, has been expended in furnishing the institution and Mrs. F. Wrench has given as her contribution a bed and mattress worth about £37.

Proposed Sanatorium in Belfast.

The public health committee agreed at its meeting on July 7th to recommend the Belfast city council to erect a sanatorium for 100 consumptive patients with provision for paying patients, the buildings to be of wood or iron on proper foundations. The cost of site, building, &c., will probably be close on £20,000 and the cost per bed per annum will be about £50. It does not recommend that notification of tuberculosis should be adopted as it would, it is said, cost too much money in fees paid to pathologist and medical men (from £700 to £800 per annum). The matter is to be arranged finally at an early meeting of the corporation. That the matter has proceeded so far is really due to the unwearied efforts of Mr. Robert Brown (secretary of the Ulster Society for the Prevention of Tuberculosis) and the decided action of the Local Government Board in pointing out to the public health committee its obvious duty in the matter.

The Cowan-Heron Hospital at Dromore.

At the fourth annual meeting of the supporters of this institution, held on July 7th, it was reported that there were at the beginning of the year 1903 six patients and since then 56 had been admitted—that is, there were 62 patients in all treated during the year. Most of the cases were medical. Mr. W. Cowan-Heron, the generous donor of the hospital, has presented outdoor shelters for patients. The income for the year was £307 18*s*. 3*d*. and the expenditure was £291 0*s*. 8½*d*., leaving a balance of £16 17*s*. 6½*d*.

The Small-pox Epidemic at Limavady.

At a meeting of the Limavady board of guardians held on July 11th the chairman reported that the last small-pox convalescent was leaving hospital that day.

July 12th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Prevention of Dust on Roads.

AT a meeting of the Academy of Medicine held on June 28th Dr. Guglielminetti of Monaco read an important paper on the application of tar and tar products to roadways. Dr. Guglielminetti has done much to encourage this practice in France. At the present day the tendency is to use not tar itself but westrumite, which is a mixture of the heavy oils of tar emulsified by means of ammonia; a proportion of it, amounting to 5 or 10 per cent., is added to water which is then spread on the roads by an ordinary water-cart. The process is not expensive (12 centimes per square metre) and three or four consecutive waterings appear to produce a lasting effect. Moreover, the use of tar, or rather of tar oils, was attended by two inconveniences which it is hoped will not occur with westrumite. These were (1) that on roads having a gradient of more than 3 in 100 a tarry layer which was slippery for horses formed on the surface and (2) that in order to obtain good results it was necessary to have a succession of fine days and roads perfectly dry and in good condition. For the purpose of making a satisfactory comparison one half of one of the great "avenues" of Paris has been treated with tar and the other half with westrumite. It has already been ascertained that air collected on the surface of ground treated in this way contains exactly half the number of germs found in air collected on the surface of an ordinary road.

Tuberculous Children in the Hyères Sanatorium.

At the same meeting of the Academy of Medicine M. Vidal made a communication from which it appeared that the proportions of the sexes among the children admitted were 345 girls and 272 boys—i e an excess of 73 among the girls Of these girls 210 suffered from bronchitis and similar conditions and 135 from pulmonary tuberculosis The girls represented 55 per cent of the total cases of bronchitis and other affections of the same group, and 57 per cent of the total cases of pulmonary tuberculosis

Successful Treatment of Fractured Femur with Metallic Hooks

At a meeting of the Surgical Society held on June 29th M Dujarier showed a man, 30 years of age, on whom this method had been used, radiographs taken some before and others after the treatment were also shown The fracture was at the junction of the upper third and middle third of the femur and there was considerable overlapping of the ends of the bones After making an incision completely reducing the fracture and removing a splinter of bone M Dujarier united the broken ends of the bone by means of a metallic hook (*agrafe métallique*) The result was perfectly successful and a radiograph taken two months after the operation showed the two fragments united end to end without the slightest deformity There was no shortening and the man walked without any limp

Opotherapy in the Treatment of Cirrhosis of the Liver

At a meeting of the Therapeutical Society held on June 22nd M Hirtz showed a patient who had improved considerably under hepatic opotherapy On admission to hospital he suffered from œdema and pronounced ascites The liver was small the spleen was large and the collateral circulation was well marked The patient was put on milk diet to which were added 120 grammes of fresh pig s liver bruised into soup Four litres of fluid were removed by paracentesis and fluid continued to flow from the wound for several days The amount of urine rose rapidly from 400 grammes to 2000, 2500 and 3000 grammes a symptom which was very favourable in respect of prognosis The œdema and the collateral circulation gradually disappeared and there was no more formation of ascitic fluid It was well known that the results of this kind of treatment were not always so good as those now described and up to the present time no means had been found for distinguishing the cases in which opotherapy would succeed

Resection of the Knee for Bacterial Osteo arthritis

At a meeting of the Sociéte de l Internat des Hopitaux de Paris held on June 23rd M Peraire showed a middle aged man whose knee joint he had resected eight years ago for bacterial osteo-arthritis The patient had previously been treated without any benefit by splints, blisters and application of tincture of iodine It was necessary to remove 13 centimetres of bone substance, the result was satisfactory and the patient used a sole of only 8 centimetres in thickness

Temperature of the Body obtained from the Urine

M Mantoux discussed this subject at a meeting of the Société Médicale des Hopitaux held on July 1st He has found that in the human subject the taking of temperature in the urine is both easy and more correct than any other procedure used for the purpose except the method by the rectum, all that is required being that the person should micturate on the bulb of a registering thermometer The differences between temperatures taken in this way and those taken in the rectum very seldom exceeded 0 5° C and were due either (1) to faulty methods of observation, such as insufficient micturition and imperfect sensibility of the thermometer or (2) to physiological retardation of the variations of the central temperatures This retardation depended on the quantity of the urine and on the rapidity with which the central temperature varied Without being applicable in all cases the taking of body temperature in the urine might be of real service. By its convenience and accuracy it was specially indicated for use by tuberculous patients who often had to take their temperatures several times a day for long periods In these patients it would provide a means of avoiding errors due to psychical causes but, on the other hand, it would give no information as to the sudden and transitory variations in temperature which in some cases followed muscular exercise

Military Law and Medical Men

The Chamber of Deputies has been discussing the Military Bill (*Projet de Loi Militaire*) reducing the duration of service in the active army to two years and has agreed to Article 24 which refers to medical students It provides that medical men and medical students who have kept 12 terms and at the end of their first year of service have passed the examination of *médecin auxiliaire* shall receive this appointment and shall complete their second year of service as *médecins auxiliaires* The conditions applicable to the medical service of the army are defined by Article 25 which provides that candidates for the medical department of the army (*élèves en médecine du Service de Santé Militaire*) and students of the military veterinary schools bind themselves from the time of entering the schools to serve in the active army for six years at least (dating from the time of leaving the schools) if they have passed the leaving examinations and for three years at least if they have not passed these examinations Both classes immediately on leaving the school shall have two years of service with troops on the terms previously set forth in the article The first category then enter either the École d Application du Service de Santé Militaire as aides majors of the first class or the École d Application de Cavalerie as aides vétérinaires of the first class The second category if before the termination of their engagement they succeed in passing the examinations which admit to the rank of aide major or aide vétérinaire finish their two years of active service with troops under the conditions of Article 24 and then enter at Val de Grace or at Saumur as aides majors or aides veterinaires Similar regulations are applicable to the students of the Naval School of Médicine

Chair of Experimental Pathology

Professor Chantemesse having been at his own request transferred to the chair of hygiene, vacant through the death of Professor Proust the chair of experimental patho

The council of professors, 33 in

July 7th for the purpose of con-

ites Four names were submitted —namely those of M Achard M Netter, M Roger and M Widal At the first selection M Roger and M Widal each received 10 votes while 6 were given to M Netter and 7 to M Achard At the second selection M Roger received 17 votes and M Widal 13 votes M Roger has therefore obtained the first place He was interne in 1883, took the degree of M D in 1887, and became hospital physician (*médecin des hopitaux*) and *agrégé* in the Paris Faculty of Medicine in 1892 Although only 44 years of age he has already accomplished an extensive and varied amount of scientific work in addition to which he enjoys an unquestioned celebrity in the scientific world

July 11th

VIENNA

(FROM OUR OWN CORRESPONDENT)

Symptomatology of Urosepsis

IN a paper on Urosepsis read by Dr Ferdinand Kornfeld at a recent meeting of the Gesellschaft der Aerzte he said that the effects produced by urosepsis consisted partly of local symptoms connected with the uropoietic apparatus and partly of general symptoms due to urine poisons circulating in the blood In clinical work the latter conditions—i e, those of septic origin—were liable to receive more consideration than the local symptoms When the general septic phenomena predominated the diagnosis of cryptogenic septicæmia was not unlikely to be made In addition to abnormal states of the bladder the characteristic symptoms of urosepsis were (1) urine fever which might be isolated and acute, recurring, or chronic, (2) intestinal disturbances, and (3) phenomena of nervous origin In chronic urosepsis the disease followed a regular course without fever and was marked by serious impairment of the general health with debility and emaciation but without pronounced local symptoms Cases of isolated cachexia often belonged to this class The cachexia when severe might easily be mistaken for malignant internal disease especially for carcinoma of the intestine, if gastric intestinal symptoms happened to be present, such as gastric-dilatation, resistance in the pyloric region, deficiency of free hydrochloric acid presence of lactic acid, vomiting and intolerance of solid food In the circulatory and respiratory system urosepsis might cause cardiac arhythmia and irregularity without anatomical changes in the valves or myocardium, stases in the circulation, cyanosis, localised pneumonia, and localised atelectasis. In the skin it might cause indurations, infiltrations, phlegmonous ulcerations, erythema nodosum, and purpura hæmorrhagica. Hæmorrhages from the urinary tract were often brought about by the great fluctuations of pressure in the urinary and sanguineo-vascular system. Free intestinal hæmorrhage occurred occasionally. In addition to serious disorders of the central nervous system, hemicrania, tremors, and vertigo might be among the results of urosepsis. Cramps and paralytic seizures were relatively infrequent and only made their appearance in uræmia. In ten cases of symptomatic cachexia in which prostatectomy had been performed a long time previously Trousseau-Erb-Chvostek symptoms were observed. This form of tetany was to be referred to auto-intoxication from the urinary system. Another result of urosepsis was disordered action of the trophic nerves leading to bronzing of the skin, urticaria, abnormal distribution of perspiration, and detachment of the nails.

A New Hospital in Vienna.

On June 20th the foundation stone of a new hospital in Vienna was laid in presence of the Emperor. The old hospital, the celebrated Allgemeines Krankenhaus, was erected in the time of the Emperor Joseph II. and was the seat of a renowned medical school which was founded by Dutch physicians. In this hospital Rokitansky and Skoda worked and made their names famous but in course of time the buildings became out of date and no longer fulfilled the increasing requirements of modern times. The want of laboratories was felt to be a serious obstacle to carrying on scientific work and the accommodation for the patients was defective in several respects. In consequence of this the reputation of the Vienna medical school declined and no German professor accepted a call to Vienna. The desirability of building a modern hospital was suggested several years ago but the scheme has not been realised till now. The site is not far from the old hospital. A long time is certain to be required for the completion of the buildings; it is intended that the gynæcological clinic shall be erected first. The new physiological institute was opened not long ago. It has been built after Exner's plan and is well supplied with electrical apparatus and accessories of all kinds but unfortunately does not devote sufficient space to a very important branch of physiology—namely, physiological chemistry.

Post-graduate Courses.

Two series of post-graduate courses will be held during the summer in Vienna, one of them commencing on August 1st and the other on Sept. 1st. It is expected that many German and American visitors will attend. Any questions about these courses may be directed to the correspondent of THE LANCET.[1]

July 11th.

---

[1] We will forward such questions to our correspondent.—ED. L.

WATER-SUPPLY OF TEIGNMOUTH.—At the meeting of the Teignmouth (Devon) urban district council held on July 5th it was decided to sign an agreement under which Teignmouth would receive a water-supply from the new waterworks of Paignton at Holme Moor. The chairman remarked that by this agreement Teignmouth would possess a pure and abundant water-supply.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following prizes were awarded for the summer session 1904:—Barker anatomical prize (£31 10*s.*), C. Cooper. Mayne scholarship (£15), A. N. Crawford. Carmichael scholarship (£15), J. Prendiville. Gold and silver medals in operative surgery: gold, J. S. Dunne; silver, P. D. Sullivan and J. C. Murphy (equal). Stoney memorial gold medal in anatomy, J. Prendiville. Practical histology: H. C. Carden, first prize (£2) and medal; and D. Adams, second prize (£1) and certificate. Practical chemistry: R. H. F. Taaffe, first prize (£2) and medal; and F. C. Warren, second prize (£1) and certificate. Public health and forensic medicine: M. Cohen, first prize (£2) and medal; and T. H. Massey, second prize (£1) and certificate. Materia medica: F. C. Warren, first prize (£2) and medal; and J. B. Kelly, second prize (£1) and certificate. Biology: J. C. S. Day, first prize (£2) and medal; and T. C. Boyd and H. W. White (equal), second prize (£1) and certificate. The winter session will commence in October.

Obituary.

JOHN BIRKETT, F.R.C.S. ENG.

WITH the death of John Birkett, who had recently entered his ninetieth year, another link between the earlier and middle decades of the last century and the first years of the present has broken. Of the Members of the Royal College of Surgeons of England originally elected to the Fellowship he and his friend and former coadjutor, Sir John Simon, have been for some time past the last survivors. He gained that honour by no favouritism but from the position that he had made for himself amongst his compeers by hard work, careful observation, and strict attention to duty. He was a representative surgeon of the pre-Listerian period, carrying on with such improvements as his own acute observation suggested the principles and practice of surgery as it was taught by the great surgeons of the hospital of which he was for so many years a distinguished ornament. Relying on cleanliness and care and acknowledging the value of rest he appreciated because he had long perceived the value of simple treatment and it was easy for him to graft on his habitual methods the extreme attention to minute details which Lister was the first to inculcate and which has proved of such profound importance in the practice of surgery.

Mr. Birkett was born on April 14th, 1815, at 10, The Terrace, Upper Clapton, Middlesex, then occupied by Mr. Giberne. His father and mother lived in the City at 14, St. Mary Axe. He had the misfortune to lose his mother in infancy, she dying on the ninth day after his birth. His father immediately removed to 1, Lodiges-buildings, Hackney, a house adjoining large nursery gardens that were then well known. Here for five years he was carefully tended by two sisters of his father and was then sent to a school in Hackney kept by a Frenchman named Dumas, where he remained for five years. In the summer and autumn of 1825 he was at a school at Edmonton kept by a mathematician and astronomer, Dr. Firminger. From there he was sent to Mr. Elwell at Hammersmith, where he remained for three and a half years, and finally completed his school life at the establishment of the Rev. Charles Parr Burney who was a Greek scholar of repute. At this school he formed warm and lasting friendships with John Simon, John Ord, Stephen Rigaud (afterwards Bishop of Antigua), and Henry Arthur Herbert of Muckross, Ireland. Before leaving this school, where he remained for two and a half years from January, 1830, to June, 1832, he was bound apprentice in September, 1831, at the Royal College of Surgeons of England to Bransby Blake Cooper who was then surgeon at Guy's Hospital. He was one of the last, if not the very last, of the surgeons' apprentices who paid £500 for the privilege of attending the lectures and surgical practice of Guy's Hospital. He was entered as a student at that hospital on Oct. 1st, 1832, attended the introductory lecture, and was introduced to several of his teachers, amongst whom was Dr. Alfred Swaine Taylor, destined to become the most distinguished medical jurist and toxicologist in England, and who lived up to a comparatively recent date. On Oct. 6th, 1837, Birkett passed his examination as a Member of the College, being examined by Sir Astley Cooper, Sir Anthony Carlisle, and Mr. Guthrie, and at the same time became demonstrator of anatomy in the hospital, having as a colleague James P. Babington.

At Christmas, 1840, he rented 2, Broad-street Buildings and Dr. Babington having resigned Mr. Thomas Moody was associated with him as demonstrator of anatomy, their names appearing for the first time on the list of teachers at the hospital for the session 1841–42. On August 26th, 1844, in recognition of his position and abilities, he was elected Fellow of the Royal College of Surgeons of England by the Council. In 1845–46, Mr. Moody having resigned, he was joined by Alfred Poland, and this year undertook to give demonstrations of the anatomy of the tissues with the microscope, or, as it would be now termed, demonstrations in histology, marking very distinctly the period when the use of the microscope began. In 1847 he continued these demonstrations, resigning the demonstratorship of anatomy, and he was appointed to make the post-mortem examinations.

In May 1849 he was elected assistant surgeon to Guy's Hospital and in the same month and year was awarded the Jacksonian prize for an essay on Diseases of the Mammary Gland an extremely well written and suggestive work which besides the valuable money consideration of £300 established his position as an accurate clinician and brought him into relation with many leaders of the profession outside the walls of his own hospital In 1849, in order to be in closer proximity to the hospital, he migrated to Wellington street Southwark, on which side of the Thames also his practice was then chiefly situated In 1851 having previously relinquished the post of demonstrator of morbid anatomy he commenced the delivery of anatomical lectures with Mr Hilton After serving the hospital as assistant surgeon for the short period of four and a half years he was in September, 1853 elected to the much coveted position of surgeon to Guy's Hospital When Mr Bransby Cooper became incapacitated by serious indisposition from lecturing on surgery Mr Birkett delivered his lectures for him On the death of Bransby Cooper Mr Cock declined to lecture and the lectureship was offered to Mr Hilton who, however, preferred to deliver the lectures on anatomy It was then naturally offered to Mr Birkett who accepted the appointment and at a month's notice undertook the delivery of a course in conjunction with Mr Poland and was appointed in association with him one of the lecturers on surgery In 1856 his practice having increased he felt himself able to meet the expenses of a residence in the West end and took a house in Green street in which he lived for 40 years He continued to lecture on surgery and to perform the duties of surgeon at Guy's Hospital until April 1875 when having attained the age of 60 years, he retired in accordance with the rules of the hospital In the meanwhile, in 1867 he had been elected a member of the Council of the Royal College of Surgeons of England and retained that office until 1883 In 1869 he was appointed Hunterian professor of surgery and pathology at the College and in that and the following year lectured on the Nature and Treatment of New Growths He was elected a member of the court of examiners in 1872 and served in that office till 1882 He was an examiner in anatomy and physiology from 1875 to 1877, and examiner on the board of examiners in dental surgery from 1875 to 1882 He served as Vice President of the College for two years in 1875 and 1876 and in 1877 he became the President [illegible] in his profession [illegible] discharged the [illegible] Home Office [illegible] the anatomical schools in the provinces and that in the discharge of his duties in that capacity he gave entire satisfaction both to the officials at headquarters and to the teachers of anatomy in the several schools

Though not a voluminous writer Mr Birkett published several works which are still referred to by those interested in the special subjects with which they deal The essay which gained the Jacksonian prize to which reference has already been made was issued in 1850 as an octavo volume He had previously translated Alfred von Behr's 'Handbook of Human Anatomy, General Special and Topographical in 1847 A Description of some of the Tumours removed from the Breast and Preserved in the Museum of Guy's Hospital, London and Contributions to the Practical Surgery of New Growth, or Tumours, and Cysts were others of his works He was also for some time editor of the Guy's Hospital Reports He wrote the article on Hernia and that on Diseases of the Breast in Holmes's System of Surgery He was a founder of the Pathological Society of London of which he was a councillor in 1851 and a Vice President in 1860 62 At the Royal Medical and Chirurgical Society he was secretary during the years 1863–65 on the council in 1867 68 and treasurer from 1870–73 He took an active part in the discussions at these societies and made many communications to both of them which are to be found in their respective Transactions He was for many years one of the medical referees of the London Life Assurance while for 40 years he was a member of the Royal Institution attending the lectures with much assiduity, thus keeping himself *au courant* with modern research He took a warm interest in the affairs of the Worshipful Company of Ironmongers to which body he was affiliated in 1842 and after passing through subordinate offices became Master in 1871 He was again elected Master in 1892 and for some time before his death was the "Father of the Company He had the pleasure of seeing his son, Mr Percy Birkett, also fill the office of Master

Mr Birkett without any pretension to being a classic or a mathematician—he had been, as we have seen, at too many schools for this—was a man of wide and liberal education and was endowed with powers of keen observation and of impartial judgment He was not a professed botanist but was familiar with most of our wild flowers and knew the English orchids well whilst his long association with the Royal Botanic Society and the Regent's Park Gardens and his frequent visits to Kew made him acquainted with the names and origin of many exotics the structure of the flowers or leaves of which especially if of Alpine habitat, with lens in hand he would pore over for an hour or more, taking them home to study and to identify at leisure His habit of spending his holidays in wanderings on the continent especially in Switzerland, and of visiting the chief galleries of painting on the continent, together with his excellent memory and his intercourse with various artists, rendered him a good judge of pictures and added to the charm of his conversation and reminiscences of foreign cities Few men knew better how to use a map To form one that could be serviceable and easily consulted even if the walk were no longer than from Sevenoaks to Maidstone or from Midhurst to Haslemere he would make the starting point the centre by joining two or if need be, more ordnance survey maps Then after bevelling the edges that the junction might be almost invisible colouring the areas of equal height describing concentric circles increasing in diameter by two or more miles mounting on linen and constructing a case no whit inferior to that sold in the map sellers shops he was secure from losing his way in his peregrinations

The success attending his operations which was exceptional both in private and in hospital practice, was mainly due to the attention which he paid to the most minute particulars in the dressing of wounds and to the comfort of the patient In these respects he is said to have been rather a trial of temper to the numerous house surgeons who worked under him No slipshod bandaging was permitted Singularly neat and precise himself he could not endure irregularity want of consideration or incapacity in others and spent an inordinate though from the point of view of a teacher surely not wasted time in seeing that his directions for the comfort of the patient were carried out in the minutest detail His large knowledge of diseases of the female breast led him to be consulted frequently both by his colleagues in the hospital and by the public and he was held in high estimation not only for his opinion but for his operative skill His success would probably have been greater had he not been of a shy and reserved disposition with much of the stateliness and courtesy of the old school but totally lacking in the push and go which would have rendered conspicuous men of far less ability In full accordance with this it may be remarked that he rather prided himself in carrying on his practice when at its best without burdening himself with the expense of a carriage He used to maintain that many of the younger men of the present day were too luxurious and that unless they possessed private means it was far more economical and certainly more wholesome to walk than to drive to and from the hospital Many of the older surgeons and physicians of his earlier years never thought of driving or of being driven to their work Tall spare in figure, always neatly and well dressed and walking with head erect and elastic step, he supported his theory by his practice and enjoyed excellent health to the age of 80 or more

Of late years there were not wanting signs that the machinery of his body was wearing out In April 1902 he suffered from an embolism of his left femoral artery and shortly after lost the vision of his right eye for a few minutes from embolism or spasm of the retinal artery Perfect recovery took place from the latter condition but a relapse of shorter duration occurred on one if not two occasions Two months after the occlusion of the femoral artery pulsation in the dorsal artery of the left foot was imperceptible and the foot was cold His chief ailment was however calculus in the pelvis of the kidney on one or both sides which led him to lie in bed during the last two or three years of his life to prevent pain and hæmorrhage He bore his ailment very patiently, his strength failed he became unconscious and passed quietly away in the midst of his family, full of years and well-deserved honours

Mr. Birkett married in 1842 Lucy Matilda, the daughter of Halsey Jansen, and leaves four sons and a daughter.

WILLIAM ALEXANDER McKEOWN, M.D. R.U.I.

IT is with regret that we announce the death of the well-known Ulster ophthalmologist Dr. W. A. McKeown, which took place suddenly on July 9th from syncope at Newcastle, County Down, his summer residence. He belonged to a medical family, his father being the late Dr McKeown, a well-known medical practitioner of Ballyclare, County Antrim. When a young man he went to Belfast where he at first entered a solicitor's office and having acquired the art of writing shorthand he was for a time engaged in journalistic work. However, his tastes were in another direction and he entered Queen's College, Belfast, as a student of medicine in the session 1865-66. His career there was marked with the greatest distinction; he held a scholarship in his second and third years and a double scholarship (in anatomy and physiology and in therapeutics and pathology) in his fourth year. In 1869 he graduated as M.D. of the Queen's University, being at the same time a gold medallist and first of first honours. He subsequently studied in Dublin, Paris, and London, taking a special interest in ophthalmic work. Returning to Belfast he devoted himself to the eye, ear, and throat as his subjects. Through his exertions the late Mr. George Benn founded the Ulster Eye, Ear, and Throat Hospital in 1871 and in 1874 the new buildings were opened. His work at this hospital soon brought him into marked prominence in Belfast and the North of Ireland, where his name became a household word and his originality and brilliant work attracted attention among ophthalmic surgeons. His first original contribution was in reference to the introduction of the magnet for the removal of particles of iron or steel lodged in the interior of the eye, an accident of frequent occurrence in the numerous manufactories and shipyards in Belfast. Probably, however, it was in connexion with the treatment of cataract that his reputation was established and his name will live in connexion with his operative methods for removing immature cataracts. He was the author of a "Treatise on Unripe Cataract and its Successful Treatment by Operation, with Tables of 152 Cases." At the annual meeting of the British Medical Association in Belfast in 1884, when he was president of the section of ophthalmology, he demonstrated this method, and shortly before his death he had received and accepted an invitation from the ophthalmic surgeons of the Johns Hopkins Hospital at Baltimore to go to America and demonstrate his operation before a congress of American ophthalmic surgeons. His hospital was constantly visited by ophthalmic surgeons from all parts of the world to see his numerous original methods of operative work. He contributed papers to the Clinical Society, Ophthalmological Society, and the various medical journals. He was an ex-president of the Ulster Medical Society and of the Ulster branch of the British Medical Association, and to the meetings of both these medical societies he was constantly sending contributions. In 1896 he was appointed the first lecturer on ophthalmology in Queen's College, Belfast.

Dr. McKeown, while admittedly one of the first ophthalmologists of his time, did not limit his attention to the narrow groove of medical specialism. He was interested in all branches of education. He was elected by the graduates of the Queen's University one of their representatives on the Senate and when the step was taken of destroying that University and replacing it by the existing Royal University he was appointed an original Crown senator, and he constantly used his great influence to advance the interests of the Northern Medical School in Belfast. He entered very strongly into the recent discussions on Irish educational questions, being a very pronounced advocate of non-sectarian education and however much some might differ from him in opinion all acknowledged his great ability, fearless honesty, and intense earnestness. His work in directing attention to the insanitary condition of the primary national schools was of the greatest importance.

Dr. McKeown was a man of great force of character, straightforward, honest, a hater of shams and of all unreality. He was a born fighter, utterly fearless, and if he was in a minority this made no difference—it simply stimulated him to fight the harder. As a result of his great controversial powers and his merciless exposure of all humbug he was both feared and respected. He leaves a widow and one child (a daughter) to deplore his death which took place at the age of 60 years. He was buried in the Belfast city cemetery on July 11th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Ladislaus Niemilowicz, professor of medical chemistry in the University of Lemberg, at the age of 41 years.—Dr. Victor Cnyrim of Frankfort, whose name is well known in connexion with various questions of hygiene and of medical politics.—Dr. L. de Reynier of Neuenburg, who is described as the Nestor of Swiss medical men, at the age of 95 years.—Dr. Le Roy des Barres, surgeon of the St. Denis Hospital, Paris.—Dr. Joao Pizarro Gabizo, professor of dermatology in the University of Rio de Janeiro.—The *Sviet* announces the death of the Russian Court accoucheur, Ivan Fedorovitsch Maslovski, a scientific gynæcologist, an experienced operator and consulting physician at the Maximilianovski Infirmary, and an active member of the Gynæcological Society.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination held recently the following candidates passed in the subjects indicated:—

PART I.

Royal Free Hospital; and B. R. Shillitoe,

sco-Owen, Cardiff; and G. F. C. Harvey, London Hospital.

Materia Medica and Pharmacy.—F. M. Cunningham, Royal Free Hospital; C. J. Evans, St. Bartholomew's Hospital; and C. S. Spencer, Manchester.

PART II.

Anatomy.—A. E. Blythman, Charing Cross Hospital; R. B. Dawson, Guy's Hospital; W. P. Pinder, Leeds; S. K. Poole, Guy's Hospital; W. E. N. Smith, Durham, and C. J. Wolfe, Edinburgh.

Physiology.—A. E. Blythman, Charing Cross Hospital; R. B. Dawson, Guy's Hospital; R. J. W. McKane, Leeds; C. J. Wolfe, Edinburgh; and R. P. Wylde, Manchester.

UNIVERSITY OF BIRMINGHAM.—The following is a list of the successful candidates in the Faculty of Medicine:—

I. *Degree of Doctor of Medicine.*—(*a*) Official: John Douglas Stanley (*b*) Under Ordinary Regulations: Jordan Lloyd.

II. *Degree of Master of Surgery.*—Official: John Thomas Hewetson and Thomas Wilson.

III. *Degrees of Bachelor of Medicine and Bachelor of Surgery.*—(*a*) Associate: Alex. Wathen Nuthall. (*b*) Past students of Birmingham Medical School: Tom William Beazeley, Charles York Flewitt, Sidney Cameron Lawrence, and William Arthur Loxton. (*c*) Under Ordinary Regulations: Alfred Ernest Remmett Weaver (scholarship), William Cook, Cuthbert Keay Gettings, and Leonard George Joseph Mackey.

IV. *Fourth Examination for the Degrees of M.B., Ch.B.*—Class I.: Norman John Launcelot Rollason (scholarship). Class II.: Robert Wallace Aitken, Reginald Hudson Astbury, Edward Lancelot Bunting, Fred Thomas Hollway Davies, Helen Gertrude Greener, Leonard , William Cuthbert Houghto Ravenhill, Herbert Henry W

V. *Third Examination for the Degrees of M.B., Ch.B.*—Class I.: Frederick Wilkinson (scholarship). Class II.: Robert Wallace Aitken, Reginald Staines Austin, Edward Lancelot Bunting, Davies, Helen Gertrude Greener, Leonard Chattock Hayes, Arthur Cecil Hincks, William Claude Horton, William Cuthbert Houghton, Harold Bruce Jones, Thomas Holmes Ravenhill, Walter Rowland Southall Roberts, Norman John Launcelot Rollason, Spencer Graham Walker, and Herbert Henry Warren.

VI. *Second Examination for the Degrees of M.B., Ch.B.*—Class II.: John Dale (scholarship), James Fenton, Nevill Coghill Penrose, and David Priestley Smith.

VII. *First Examination for the Degrees of M.B., Ch.B.*—Class II.: John Adams, Charlotte Bailey, Harold Gordon Browning, John Selwyn Edwards, George Henry Chavasse Mold, George Bassett Moon, Arthur McLean Pickup, John Lichtenstein Ritchie, Herbert Henry Sampson, Harold Cairns Terry, Ethel Annie Waldron, and Edward Vernon Whitby.

VIII. *Degree of Bachelor of Dental Surgery.*—Henry Percy Pickerill.

IX. *Diploma in Public Health.*—Parts I. and II.: Thomas Dawson.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS.—The following candidates have passed the first professional examination:—

Honours.—T. C. Boyd, T. P. Cormack, J. C. E. Day, C. Hyland, G. Patton, W. G. Ridgway, A. Sheridan, and H. W. White.
In all Subjects.—G. E. Beggs, G. Collins, J. J. Cuskelly, G. A. Finegan, J. A. J. Flannery, M. J. Hawkshaw, F. N. Holden, D. J. Hurley, H. W. Kay, W. J. P. Lillis, D. J. Lyne, T. J. Lyons, J. McHugh, J. T. McKee, P. Maguire, J. P. Morgan, T. N. Neale, E. Ryan, M. J. Saunders, H. B. Sherlock, J. M. Smyth, C. H. Stringer, and W. C. Townsend.
Completed Examination.—S. W. Hudson and T. J. McDonnell.

FOREIGN UNIVERSITY INTELLIGENCE.—*Lyons:* Dr. Ance[illegible] of Anatomy, Dr. Nev[illegible] Natural History, Dr. [illegible] Chemistry, and Dr. [illegible] —*Montpellier:* Dr. E. O. Gyrnfelt has been appointed *professeur agrégé* of Anatomy and Dr. Gagnière *professeur agrégé* of Physics.—*Nancy:* Dr. Laborde has been appointed *professeur agrégé* of Chemistry, Dr. Weber *professeur agrégé* of Anatomy, and Dr. Mathieu *professeur agrégé* of Physiology.—*Paris:* Dr. Branca has been appointed *professeur agrégé* of Anatomy and Dr. Maillard *professeur agrégé* of Chemistry.—*Toulouse:* Dr. Dieulafé ha[illegible] of Anatomy and Dr. Aloy [illegible] *Tubingen:* Professor Erns[illegible] appointed Director of th[illegible] Dr. Krehl who goes to [illegible] recognised as *privat-docen*[illegible] *Vienna:* Dr. Anton Bumm, editor of the *Wiener Medicinische Presse*, has been recognised as *privat-docent* of Surgery and Dr. Josef Sorgo as *privat-docent* of Internal Medicine. Dr. August Ritter Vogl v. Fernheim, Professor of Pharmacognosis, is about to retire.

COUNTY OF DURHAM MEDICAL UNION.—The sixth annual meeting of this union was held at the Town Hall, Durham, on June 28th. There was a large attendance of members from the districts of Chester-le-Street, Wingate, West Hartlepool, Durham, South Shields, South Moor, Sunderland, Stanley, Darlington, Crawcrook, Ryton, Willington, Evenwood, Easington, Birtley, West Auckland, Whickham, Low Fell, Washington, Sherburn, Ryhope, Wrekenton, &c In the absence of the President, Dr. E. Jepson (Durham), Mr. W. Galloway (Wrekenton) was voted to the chair. Dr. Jepson was again re-elected president and Dr. J. Murphy (Sunderland) was re-elected vice-president. The council for the ensuing year was also elected. Messrs. Graham and Shepherd (Sunderland) were re-elected secretaries and solicitors. Votes of condolence were passed to the relatives of the late Dr. C. F. G. Mann (Washington) and Mr. A. W. Attwater (Whickham) who had both been active members of the union. The report of the council for the past year was read and was considered to be very satisfactory. The secretaries of the various local committees and others made verbal reports as to the position of union matters in their respective districts which were also of a satisfactory nature. The question of the National Deposit Friendly Society was again considered and it was resolved, on the motion of Mr. R. Stuart (Durham), seconded by Dr. Johnson (South Moor),

> [illegible] ere rigidly to the resolution [illegible] and Northumberland Unions [illegible] *Friendly Society* in any way [illegible] members to sign the certifi-[illegible]

Dr. Jepson, Dr. Murphy, Dr. J. H. Hunter, and Dr. R. S. Hubbersty were re-elected as the representatives of the union on the judicial committee of the Durham and Northumberland Unions. A discussion afterwards took place in reference to applications from certain miners' lodges for a reduction of the fortnightly subscription and after the matter had been most carefully considered it was unanimously resolved, on the motion of Dr. J. H. Hunter (South Shields), seconded by Mr. E. H. Davis (West Hartlepool),

> That this meeting sees no reason to alter the determination of the union previously arrived at that the sum of 9*d.* per fortnight is the least fortnightly subscription that can be accepted for colliery or family club contract practice.

A hearty vote of thanks to Mr. Galloway for presiding and to Dr. Jepson for his presidency during the year brought to a close a most successful meeting.

TRINITY COLLEGE, DUBLIN.—The following awards were made in Trinity term:—Surgical travelling prize: John S. Joly. FitzPatrick scholarship: James G. Wallis. Medical scholarships: in anatomy and institutes of medicine, Thomas O. Graham (Trinity College) and Francis O'B. Ellison (Stewart); in physics, chemistry, botany, and zoology, Allman J. Powell (Trinity College) and George F. Graham (Stewart). Purser medal: Francis R. Coppinger.

AN OPHTHALMIC INFIRMARY FOR KASAN.—The Kasan local council is taking steps to establish a central ophthalmic hospital to deal with the exceptional number of cases of diseases of the eye occurring in the district and found chiefly amongst the foreign settlers.

DONATIONS AND BEQUESTS.—Mr. and Mrs. John Dyer of Swansea have given a sum of £2000 towards the endowment of the Devon and Dorset Ward of the Swansea General and Eye Hospital.—The Royal Westminster Ophthalmic Hospital has received, under the will of the late Miss Steel, a legacy of £1000.

LONGEVITY.—Mrs. Hannah Coleman of Cleeve, Yatton, Somersetshire, celebrated her 103rd birthday on Feb. 22nd.—Mr. Joseph May, who took the diplomas of M.R.C.S. Eng. and L.S.A. in 1830 and died at Devonport on April 10th, had seen the four Napoleons. The first he saw on board the *Bellerophon* in Plymouth Sound in 1815, the second at Vienna, and the third and fourth—i.e., Napoleon III. and the Prince Imperial—at Mount Edgcumbe Park.

THE LATE MR. A. K. CROSSFIELD.—Mr. Arthur Kyffin Crossfield died at his residence, Newcomen Lodge, Dartmouth, Devon, on July 5th, after a few days' illness from appendicitis. The deceased, who was in his fifty-second year, was the eldest son of the late Mr. R. Crossfield of Douglas, Isle of Man. He received his medical education in Edinburgh and took the qualifications of L.R.C.P., L.R.C.S., L.M. Edin. in 1878. After holding a resident appointment at the Isle of Man General Hospital Mr. Crossfield commenced practice at Dartmouth. He took great interest in the volunteer movement, was surgeon-lieutenant-colonel in the 2nd Devon Royal Garrison Artillery Volunteers, and was shortly to have received the volunteer long service medal. Mr. Crossfield was a justice of the peace for the borough of Clifton-Dartmouth-Hardness, and at the Dartmouth police-court on July 6th a vote of condolence with his widow and family was passed unanimously.

UNITED HOSPITALS ATHLETICS.—At Stamford-bridge, London, the thirty-eighth annual athletic meeting of the United Hospitals took place on July 9th, when the holders of the challenge shield (St. Bartholomew's Hospital) were beaten by London Hospital, whose representatives, counting ten points for a win and three points for a second, compiled a total of 49 points to 46 by the holders, while Guy's Hospital took third place with 45 points. St. Bartholomew's Hospital was successful in putting the weight, in the mile race, in the three mile race, and in the 100 yards race. The London Hospital was successful in the 220 yards, in the long jump, in the 120 yards hurdles, and in the half-mile race. Guy's Hospital was successful in the high jump, in throwing the hammer, and in the quarter-mile race.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, JULY 6TH.

Police Fees for Medical Services.

Mr. ROBERT AMBROSE asked the Home Secretary whether his attention had been called to complaints made by medical practitioners within the metropolitan area of the inadequacy of the fees paid by the police for medical services and the difficulty and expense incurred before obtaining those fees and, if so, whether, in view of the time involved in these police calls, which were generally cases of injury or poisoning, he could arrange that the fees should be increased and should be paid on demand at the local police [illegible] DOUGLAS [illegible] stand that [illegible] regard to [illegible] rvices and [illegible]

Report of Army Medical Department.

Mr. CHARLES HOBHOUSE asked the Secretary of State for War what was the cost of preparing the annual report of the Army Medical Department; at what date the report was generally presented; what was the cause of the delay in its presentation to Parliament; and whether it would be possible to expedite it in future.—Mr. ARNOLD-FORSTER answered: The cost of the printing and paper of the Army Medical Department report falls upon the Stationery Office Votes. It naturally depends on the size of the report but I have ascertained that the cost of the report recently published may be taken as about £180. The report is generally presented 18 months after the year to which the returns refer. It was explained to the honourable Member last year, in reply to a question, that many of the returns do not reach this country till the late autumn owing to the labour of compilation and that a considerable period is required for the elaboration of the report from these returns. I am afraid, therefore, that it is not practicable to expedite its publication.

THURSDAY, JULY 7TH.

Outdoor Medical Relief.

Sir WALTER FOSTER asked the President of the Local Government Board whether he would take steps to have a report made by the inspector now investigating the arrangements for outdoor medical relief in the metropolis on the number of unions, if any, in which medical relief was granted on loan in the first instance, and on the practice of requiring applicants for medical relief to attend before the board or a committee, with a statement of how long such practice had been in force and its effects on the number of applications.—Mr. LONG said: I will take steps to give effect to this suggestion as far as may be practicable.

Purity of Food.

Sir CUTHBERT QUILTER asked the President of the Local Government Board whether, in pursuance of its powers, the Board proposed to take action on the lines recommended by the Royal Commission on Arsenical Poisoning in Part VIIIA. of its report, by the appointment of a special expert officer or otherwise for securing better control over the purity of chemically prepared, preserved, or other foods liable to contain deleterious substances; and whether progress had been made in giving effect to the further recommendation of the Royal Commission that the principle of officially prescribed food standards already enforced in the case of certain articles of diet should be applied to other foods and beverages.—Mr. LONG replied: I have not at present decided to appoint a special expert officer of the kind referred to. The consideration of the recommendations of the Royal Commission is being proceeded with, and in connexion with it the proposal with regard to the appointment of such an officer will receive attention. Effect, however, could not be given to the recommendations as to food standards without legislation.

THE SELECT COMMITTEE ON THE REGISTRATION OF NURSES.

The Select Committee of the House of Commons appointed to consider the expediency of providing for the registration of nurses has now commenced its sittings under the chairmanship of Mr. H. J. TENNANT. On Thursday, July 7th,

Dr. BEDFORD FENWICK gave evidence. He pointed out that at present there was no uniformity in the training of nurses and that the public had no means of discriminating between the good and bad, efficient and inefficient. Unless a nurse possessed technical knowledge she was unable to carry out efficiently the duties intrusted to her by the medical man and she was unable to report to the medical man what particular symptoms the patient had shown during his absence. A large number of those who were following the profession of nursing were unable to take the pulse and temperature properly. He would not have separate classes of medical, surgical, and obstetric nurses; every nurse should, in his opinion, have a general knowledge of these three branches and she might afterwards specialise on that basis. There [illegible] o were engaged in nursing in the Unite[illegible] that at least 40,000 had not had any ad[illegible] lered it essential that Parliament should p[illegible] uniform training and to prevent the great danger that now existed from the want of control. He did not think that there was any fear of opposition from the nurses to examination and registration because these would raise the status of nursing.

When the Committee met on Tuesday, July 12th, the evidence of Miss Isla Stewart and Miss Margaret Huxley was heard. Miss STEWART said that she was matron of St. Bartholomew's Hospital. At present no uniformity existed in the training of nurses, each hospital having its own standard and length of training. There ought to be a certain number of years fixed and there ought also to be an examination to prove that the nurse had benefited by her training. There was a difference in the methods of St. Bartholomew's Hospital as compared with St. Thomas's Hospital. Some system of registration such as that [illegible] uced into the House of Commons [illegible] uniformity which she desired to see [illegible] ncil should be set up [illegible] The council should [illegible] of medical men and nurses but she saw no [illegible] g represented. There might be difficulties in [illegible] the cancelling of certificates for offences, but those could be overcome. Probationers were at present examined in the making of splints, making beds, their knowledge of mixing lotions for standard bottles, their knowledge of instruments, and bandaging. They were also examined in hot and cold applications, the making of poultices, the application of steam, hypodermic injections, keeping charts, and so on. She did not see why it should not be possible to obtain uniformity of examination. The attendance on the sick must be more or less the same in any hospital.

The CHAIRMAN: You would not be content with certificates from certain hospitals being approved by a central council?

Miss STEWART: I think it would be very difficult to draw the line as to what hospitals you would include. I would prefer to have the examinations carried out by one class of people.

Sir JOHN BATTY TUKE: How could such a body as that arrive at a conclusion as to what is the more important part of a nurse's qualities—her moral aptitude for the work?

Miss STEWART: That would be a question for the hospital at which she is trained.

The CHAIRMAN: What advantage would be gained from examination by a central board as against certification by the great hospitals?

Miss STEWART: I think it would prove whether all the hospitals were training their nurses sufficiently and efficiently. It would be possible, she continued, to devise examinations sufficiently varied from time to time so as to test proficiency. Elementary physiology would be one subject. Questioned by Sir JOHN BATTY TUKE, she added that this would include the bones, the position of the viscera, the main arteries, the alimentary canal, digestion, and a general elementary knowledge of the functions. A nurse ought not to work in a hospital less than three years. If she were two years in an eye and throat hospital, for instance, she ought at least to have served one year in a general hospital. Her desire was not to make examinations more severe than they were at present in the good hospitals. Probationers usually commenced at the age of 23 years but in a few hospitals they [illegible] 's the limit of age was now 35 ye[illegible] not be a limit for the granting o[illegible] t ago to be young. The public ran the risk of getting an improperly trained nurse very frequently owing to the want of uniformity. Examination by a central board would allow the public to ascertain whether they were getting fully trained nurses. It would also be an advantage to the fully trained nurse if a distinction were drawn between her and the partially qualified nurse who competed with her. The ideal they were aiming at was that there should be set up a general council with power to examine and to certify but that that should in no way interfere with the existing training that went on in the great hospitals. In answering further questions she said she believed that the employment of incompetent nurses prevailed to a very great extent.

Miss HUXLEY said that she was formerly matron of Sir Patrick Dun's Hospital, Dublin. She thoroughly agreed with the previous witness as to the necessity for uniformity in training and examination. In Sir Patrick Dun's Hospital it was the custom to bind a probationer for four years. Two years were spent in the wards and during that time the nurse received education in anatomy, physiology, hygiene, invalid cookery, and the ordinary nursing of the wards. At the end of two years she was required to go out private nursing and earned a certain amount of money for the hospital. On more than one occasion when a nurse wished to join the army nurses she had been told that she was ineligible because she had not worked three years in the hospital. She mentioned this as showing that great disappointment was caused through want of uniform practice. If a general council were to lay down the length and term of training and the form of education all nurses would have a fair start, one not being better off than another simply because she happened to be in a particular place. Want of uniformity caused great injustice. She supported generally the evidence given by Miss Stewart.

The Committee afterwards adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

AUBIN, EMILE DUPONT, M.R.C.S., L.R.C.P. Lond., has been appointed Port Health Officer for the Port of Thames, N.Z.

BARTLETT, R. C., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Act for the Romsey District of the County of Hants.

BUSHNELL, F. G., M.D. Lond., D.P.H. Cantab., has been appointed Pathologist to the Sussex County Hospital.

COLLINS, WILLIAM EDWARD, M.B. Lond., M.R.C.S., has been appointed a Member of the Senate of the New Zealand University.

HAY, JOSEPH FRANK STRONG, M.B., C.M. Aberd., has been appointed an Inspector of Lunatic Asylums, Hospitals, and Licensed Houses in the Colony of New Zealand.

JOHNSTON, HENRY M., B.A., M.B., has been appointed Chief Demonstrator of Anatomy in Trinity College, Dublin.

MENZIES, PERCY WILLIAM, L.R.C.P., L.R.C.S. Edin., has been appointed Public Vaccinator for Ohaeawai, N.Z.

PORTER, ALBERT HARDING, L.R.C.S., L.R.C.P. Edin., has been appointed Public Vaccinator for Waihi, N.Z.

REED, WALTER HUGO, M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Westbury (Wiltshire) Rural District Council.

SYMONS, WILLIAM HENRY, M.D. Brux., L.R.C.P. Lond., M.R.C.S., L.S.A., D.P.H. Oxon and Durh., has been re-appointed Medical Officer of Health for Bath.

TAYLOR, GERARD C., M.D. Cantab., D.P.H., has been appointed Medical Officer of Health of the Urban District of Finchley.

WALKER, H. J., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory Act for the Brighton District of the County of Sussex.

ZIMPEL, ADOLPH, M.B., Ch.M. Aberd., has been appointed Public Vaccinator for Ormondville and Norsewood, N.Z.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

AYR DISTRICT ASYLUM.—Assistant Medical Officer, unmarried. Salary £120, with board, apartments, attendance, and washing.

BETHLEM HOSPITAL.—Two Resident House Physicians (unmarried). Honorarium at rate of £25 each per quarter, with board and residence.

BIRKENHEAD BOROUGH HOSPITAL.—Junior Resident House Surgeon. Salary £80 and fees.

BRIGHTON THROAT AND EAR HOSPITAL, Church-street, Queen's-road.—Non-Resident House Surgeon for six months, renewable. Salary at rate of £75 per annum.

CARLISLE NON-PROVIDENT DISPENSARY.—Resident Medical Officer. Salary £150, with apartments, attendance, &c.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Two House Physicians for six months. Salary at rate of £30 per annum, with board and residence.

DORCHESTER, DORSET COUNTY HOSPITAL.—House Surgeon, unmarried. Salary £100, with board and residence.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—House Surgeon. *Salary £50 per annum, with board and washing.*

[illegible] road, S.W.—[illegible] or £40 for 12 [illegible]

GREAT NORTHERN CENTRAL HOSPITAL, Holloway.—Junior House Surgeon. Salary at rate of £30 per annum, with board, lodging, and washing. Also Pathologist. Salary 50 guineas per annum.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, also House Surgeon, both for six months, and unmarried. Salary in each case £20, with board and residence. Also Surgeon Dentist.

LIVERPOOL, TOXTETH PARK WORKHOUSE AND INFIRMARY.—Resident Medical Officer. Salary £100 per annum, with board, washing, and apartments.

[illegible] OF THE HEART, *Soho-square, W.*—[illegible]

[illegible] SANATORIUM, Mansfield.—Resident [illegible] er annum, with board, lodging, and washing.

ST. THOMAS'S HOSPITAL.—Casualty Officer for six months. Salary at rate of £100 per annum, with board and residence.

SOUTH UIST PARISH.—Medical Officer and Public Vaccinator. Salary £77 10s.

STIRLING DISTRICT ASYLUM, Larbert, N.B.—Assistant Medical Officer. Salary £150, with board, &c.

STOCKPORT INFIRMARY.—House Surgeon. Salary £100 per annum, with board, washing, and residence.

VICTORIA UNIVERSITY OF MANCHESTER.—Junior Demonstrator in Physiology.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Junior House Surgeon. Salary £50 per annum, with board, lodging, washing, and attendance.

WEST SUSSEX, COMBINED SANITARY DISTRICT.—Medical Officer of Health. Salary £650 per annum.

WALLINGFORD BERKSHIRE ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £140, rising to £160, with board, apartments, attendance, &c.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

WORCESTER GENERAL INFIRMARY.—House Surgeon. Salary £80 per annum, with board and residence.

Births, Marriages, and Deaths.

BIRTHS.

DIXON.—On July 12th, at Lynwood, Haven Green, Ealing, the wife of R. Halstead Dixon, M.B. Lond., M.R.C.S., L.R.C.P., of twin daughters.

WILLIAMSON.—On July 9th, the wife of Charles F. Williamson, M.R.C.S.E., L.R.C.P. Lond., L.S.A. Lond., of a son.

MARRIAGES.

ELLIOTT—DOWNING.—On July 9th, at St. Stephen's Church, Lewisham, Arthur Forbes Elliott, M.B., B.C. Cantab., to Mable Katharine, only daughter of Arthur Matthew Weld Downing, F.R.S.

[illegible] Worthing.

DEATHS

[illegible] Harold E. [illegible] East Africa [illegible] ann, C.B., [illegible] Boscombe, aged 39.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE ANATOMIST'S HYMN.

WE feel pleasure in congratulating Dr. Donald MacAlister on his graceful German version of the "Anatomist's Hymn" by Oliver Wendell Holmes. The original English and the German translation are published in the June number of the *Eagle*, the magazine of St. John's College, Cambridge, from which we quote three stanzas (the *second, the third, and the last) in both languages, with the permission* of the editor.—

* * * * *

"The smooth soft air with pulse-like waves
[illegible]
While all their burden of decay
The ebbing current steals away,
And red with Nature's flame they start
From the warm fountains of the heart.

[illegible]
Leaps forth to fill the woven net,
Which in unnumbered crossing tides
The flood of burning life divides;
Then kindling each decaying part
Creeps back to find the throbbing heart.

* * * * *

"O Father! grant Thy love divine
To make these mystic temples Thine!
[illegible]
And mould it into heavenly forms!"

"Sacht und gelinde die Luft, in wechselwogenden Zügen,
Leise murmelnd durchrinnt heimliche Höhlen der Brust;
Dabei hellen sich auf die purpurfarbenen Ströme,
Reger rauschen sie hin, glühen zu reinerem Rot;
Ebbet ihr Lauf wieder ab, so tragt er unmerklich von dannen
Alles, was hemmt und beschwert, alles Verfallene weg.
Rosig, wie innig erwarmt am Herde selber des Lebens,
Heiss, aus des Herzens Born, quellen sie nochmals hervor.

[illegible]
Endlich, wenn er gelabt die erschlafften verfallenen Teile,
Heimwarts schleicht er, und sucht wieder das schlagende Herz.

* * * * * * *

[illegible]

The elegiac distich employed in the translation is quite unlike the metre of the original. In German this metre is abundantly used, [illegible] is to be ill-adapted for [illegible] expressed in the follow- [illegible]

"In the hexameter rises the fountain's silvery column,
In the pentameter aye falling in melody back."

Otherwise—

"Im Hexameter steigt des Springquells flüssige Säule,
Im Pentameter dann fällt sie melodisch herab."

Dr. MacAlister many years ago gave the medical profession a proof of his familiarity with the German language when he made his excellent translation of *Ziegler's* Pathology. But to translate a manual, however technical the subject and elaborate the treatment, requires a different form of literary skill than that which is demanded for the accurate rendering of imaginative and beautiful verse into a foreign tongue. Of all languages German is, perhaps, the one that the foreigner thinks that he will find simplest to write correctly because of the many hard-and-fast rules of construction and arrangement, but the successful rendering of English into German is not often accomplished by our countrymen. We congratulate Dr. MacAlister upon his elegant feat.

TREATMENT OF PUBLIC WATER-SUPPLIES WITH COPPER SULPHATE.

THE *Engineer* of July 8th states that the United States Department of Agriculture is experimenting with a process of treating public water-supply with a solution of copper sulphate—1 part in 1,000,000 parts. The purpose of this is to destroy certain forms of algæ or plant growths which so frequently render water foul and ill-smelling; although the sanitary quality of the water is not affected the appearance, smell, and taste are such as to cause great complaint from consumers. These growths flourish best in the purest waters passed through sand filters and for this reason large storage of filtered water is not advisable unless the reservoirs are to be covered over. As to the effect upon the consumers, a person drinking three pints of water per day, with 1 part to 1,000,000 parts, would in a year have consumed only seven to eight grains of the sulphate. As a matter of fact, however, the treatment would not be continuous; two or three applications a year would probably suffice and besides this the sulphate would enter into combination with the organic life and be thus precipitated. Certain of the algæ are killed by solutions of only 1 part in 3,000,000 parts but it is possible that others will require much stronger solutions. In this case, which remains to be determined by test, the reservoir may be shut off from use during treatment or there may be a supplementary process to precipitate any copper sulphate remaining in solution.

MOTOR BICYCLES FOR MEDICAL MEN.

Beginner writes: "Will any medical man who has used a motor bicycle during winter months for professional work kindly advise if such is trustworthy in a hilly country district when the roads are heavy and the weather is rough, if it is possible to dispense entirely with a horse under such conditions, and how, if so, to keep clean and dry when visiting better-class patients?"

THE EYRE TESTIMONIAL FUND.

COFFEE-LEAF CIGARETTES.

To the Editors of THE LANCET.

SIRS,—*Can any of your readers tell me the name of a coffee-leaf* cigarette which, when smoked, causes a dislike to tobacco cigarettes, and where they can be obtained?

I am, Sirs, yours faithfully,
CASTLETON.

July 11th, 1904.

POST-GRADUATE COURSES.

OUR correspondent should consult the Students' Number of THE LANCET (Sept. 5th, 1903), p. 729, for particulars regarding post-graduate instruction which is given throughout the year at various hospitals.

THE INHABITED HOUSE DUTY REPEAL ASSOCIATION.

WE have received a visit from a representative of the committee of this association who has pointed out that a paragraph which appeared in THE LANCET of July 2nd might leave the impression upon our readers that the association was some sort of bogus or fraudulent affair. We did not intend to convey this impression, although we must confess we were not so well aware of the work of the association as we might have been considering the service that it has been to medical men. It may be remembered that the association obtained the assessment of consulting rooms used by medical men who resided elsewhere as business premises.

PICTURE POSTCARDS AND CHARITY.

THE *Daily Express* of July 7th contains the following interesting paragraph relating to this subject:—

> *One would have thought that the possibilities of the pictorial postcard had been exhausted. There is no question about its popularity, for hundreds of thousands of specimens are bought* weekly in this country alone. But the editor *of Pearson's Weekly* has discovered a new use for them and has set them to charitable purposes. First of all a collection was made of all those cards on which appeared the photographs of well-known men and women, and these celebrities were then written to asking if they would kindly sign a few which might be sold in aid of the Fresh Air Fund. The response was surprising. Hardly a refusal came to hand. The result is that *Pearson's Weekly* announces in to-day's issue a list of autograph postcards which is quite novel. Among those who have signed postcards are the following: the Duke of Norfolk, Right Hon. A. J. Balfour, Right Hon. Joseph Chamberlain, Madame Melba, Rudyard Kipling, Sir A. Conan Doyle.

Here follow the names of 34 other distinguished persons who have likewise signed postcards. We congratulate the editor of *Pearson's Weekly* on his ingenious application of the picture postcard. We believe, however, that in the employment of these postcards for charitable purposes the Assistance Publique in Paris led the way, as announced in THE LANCET of Feb. 6th last, p. 402, subsequently to the appearance of a letter in THE LANCET of Dec. 12th, 1903, p. 1699, in which a scheme to benefit hospitals through the sale of picture postcards was outlined.

CHILD-STUDY.

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent "Child-Study" in THE LANCET of July 2nd may I recommend to him the following books? Most of the literature on child-study is American. (1) Physical Nature of the Child, by Rowe; (2) Fundamentals of Child-Study, by Kirkpatrick; (3) The Study of Children, by Dr. Francis Warner (all published by Macmillan and Co.); (4) The Child, in Dent's Temple Primers; (5) The Child, by A. F. Chamberlin in Contemporary Science Series (Walter Scott); and (6) The Medical Inspection of School Children, by Leslie Mackenzie (Bell and Bradfute, Edinburgh).

I am, Sirs, yours faithfully,
W. H. COUPLAND.

Royal Albert Asylum, Lancaster, July 7th, 1904.

Beta.—There are no absolute rules. The medical officer of health should in every possible instance, to quote the words of the Local Government Board, "act in harmony with the medical attendants of the sick so as to obtain from them the valuable assistance which they can afford to him in his work." Circumstances may occur in which the medical officer of health feels it his duty to order disinfection of a patient or his immediate removal to an isolation hospital or the disinfection of premises; in such a case the medical officer of health should inform the medical practitioner of his action as soon as possible. The points raised by our correspondent and many others of a like nature were fully discussed in a series of articles entitled "Difficulties under the Infectious Diseases Notification Act," published in THE LANCET of 1895, which can be obtained in pamphlet form, price 6*d.* (by post 6½*d.*), on application to the publisher.

Lac.—The report of the Departmental Committee on Food Preservatives was issued in November, 1901, and although that is nearly three years *ago absolutely nothing has been done and* this country is still without the necessary statutory powers to control the practice of preserving foods. Briefly, the committee recommended that the use of any preservative or colouring matter whatever in milk should be counted an offence under the Sale of Food and Drugs Acts. In cream 0·25 per cent. of boric acid was suggested as permissible and in butter 0·5 per cent. Formaldehyde was forbidden altogether and salicylic acid was not to be used in greater proportion than one grain per pint of liquid food or one grain per pound of solid food.

R. S.—It is difficult to give a detailed answer on the information supplied. Many cases of eczema do [illegible] with reference to the case of the ch [illegible] *unsuitable for pulmonary cases* [illegible]. Our correspondent had better send a [illegible] of his cases to one of the local practitioners who would doubtless supply him with the information which he seeks.

R. G. J.—1. The student must either be content with the double qualification, M.R.C.S., L.R.C.P., or attend at the University as required. 2. There are so many pocket diaries of the kind required by our correspondent that we cannot undertake to make distinctions between them. 3. There are no such books, so far as we know; the facts of anatomy can only be learned and remembered by dint of steady application and dissection.

G. W., Birmingham.—On the information before us we consider that the consultant should have refused to act with Dr. B. without previously informing our correspondent. A patient has a perfect right to change his medical attendant, but the newly called in practitioner should insist upon the former attendant being informed of the change and this Dr. B. apparently failed to do.

R. H.—(1) We have no information; and (2) the best form of a "draft" balance-sheet we have seen is that given in Affleck's "Guide to the Income Tax Law and Practice," which was reproduced in THE LANCET of July 4th, 1896. This number of THE LANCET is now out of print, but the book (price 5*s.*) can probably be still obtained from the publisher, 72, Market-street, Manchester.

Monitor.—Radam's microbe killer, according to an analysis which we made a few years ago, consisted of a weak solution in water of sulphurous acid gas with traces of sulphuric acid.

Mr. J. W. Draper.—We cannot answer our correspondent's question for the reply must depend upon the regulations of the particular medical school which he may select.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private informa-
d addresses of

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1904, which was completed with the issue of June 25th, and the Title-page to the Volume, were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible *for the return of testimonials*, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all *other* Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières Paris.

Presidential Address

ON

THE GROWTH AND DEVELOPMENT OF THE OXFORD MEDICAL SCHOOL.

Delivered at the Seventy-second Annual Meeting of the British Medical Association held at Oxford on July 26th, 1904,

BY WILLIAM COLLIER, M.D. CANTAB., F.R.C.P. LOND.,

PHYSICIAN TO THE RADCLIFFE INFIRMARY, OXFORD; LITCHFIELD LECTURER IN MEDICINE AT THE UNIVERSITY OF OXFORD; AND PRESIDENT OF THE ASSOCIATION.

[Dr. Collier commenced his address by reviewing the causes which led at the early part of the nineteenth century to the neglect of medicine at the Universities of Oxford and Cambridge, and particularising the steps which were taken towards the re-establishment of medicine at the former seat of learning. He proceeded :—]

In November, 1882, Professor John S. Burdon Sanderson was appointed to the newly founded chair of human physiology and histology at Oxford, a first step towards the promotion of medical education in Oxford on modern lines. Having elected a professor of physiology, it was found necessary to build him laboratories and class-rooms for the purpose of teaching, and on June 5th, 1883, the members of Convocation were asked to grant a sum of £10,000 for this purpose. The resolution met with keen opposition, partly on the ground that vivisection would be practised and partly on the ground that the expenses were beyond the existing resources of the University. The resolution was carried by the small majority of three votes. On Feb. 5th, 1884, a decree was submitted to Convocation to empower the curators of the University Chest to raise a sum not exceeding £10,000 to defray the cost of the erection of a laboratory and class-rooms for the professor of physiology. A circular had been sent round to those believed to be opposed to vivisection, and only to those, calling upon them to show by their votes their determination not to permit experimental researches in Oxford. There spoke in favour of the resolution Dr. Liddell, the then Dean of Christ Church, and the late Sir Henry Acland, and against it the late Professor Freeman and the present Bodleian Librarian; placets, 188; non-placets, 149; and so the decree was carried. Having built the laboratories and lecture-rooms for the professor of physiology, it was found necessary to ask for an annual sum of £500 for three years to defray the cost of heating, lighting, water-supply, the salary of a demonstrator of histology, and other incidental expenses. The question of vivisection was mooted but a majority of 168 in a house of 656 decided against "the anti-physiological party," as they were called. In the same year, 1885, the Faculty of Medicine, which had been merged in natural science, was recreated, and Mr. Arthur Thomson, senior demonstrator in anatomy in the University of Edinburgh, was elected lecturer in anatomy. It needed a man of resolution and fixed purpose to cope with the situation, for when he took up his work in Oxford Mr. Thomson found himself with three students and a small wooden shed in which to teach anatomy—a great contrast to his Edinburgh experience. A sum of money was immediately collected by members of the University interested in the development of the school and a small temporary lecture room and a dissecting room were built. In the following year the curators of the University Chest built, at a cost of £500, a temporary iron-roofed building with rather more accommodation. By 1891 the lecturer's class had grown from three to 67. A sum of £7000 was now asked and obtained from the University to provide a permanent home for the teaching of human anatomy and the present excellent building, in which the Section of Anatomy will be held, was built. In a year or two, largely owing to the success of Mr. Thomson as a teacher, the lectureship was converted into a professorship.

In 1886 a most important statute was passed by which students in natural science were exempted from the first public examination in classics known as Moderations. This measure enabled students of medicine after passing their preliminary examination known as Responsions, which might be passed before coming into residence, to devote their first year in Oxford to the study of the preliminary subjects in natural science, and so another and most important barrier to the establishment of a medical school disappeared.

In 1891 Sir Henry Acland, who had always interested himself in the study of pathology and bacteriology, inaugurated a new department in bacteriology and appointed, first, Dr. Menge of Munich to take charge of it and later, in turn, Dr. Bertram Hunt and Dr. J. Ritchie. In 1895 Sir Henry Acland retired from the Regius professorship and Sir John Burdon Sanderson was appointed to succeed him, Professor F. Gotch, professor of physiology in the University of Liverpool and formerly lecturer in physiology at this University, taking Sir John Burdon Sanderson's chair. In 1896 the new Regius professor, in an open letter to the President of Magdalen, pointed out that the time had come when Oxford medical students should have the advantage of two new departments —pathology and pharmacology—both well within the scope to which Oxford had restricted itself in the building up of the medical school, and in the following year William John Smith Jerome was appointed lecturer in pharmacology and materia medica.

In May, 1898, in spite of the impoverished condition of the University Chest, Convocation passed without dissent a decree empowering the University to spend £7500 in erecting new laboratories and lecture rooms for the joint use of the professors of botany and comparative anatomy, Sir William Anson showing that this expenditure was rendered necessary by the increase in the number of medical students. In 1899 a generous medical student, Mr. Ewan R. Frazer, offered the University a sum of £5000 towards the expenses of building a pathological laboratory. This sum was accepted, the University at the same time agreeing to supplement it with another £5000, and to make an annual grant of £250 for upkeep. Two years later, in October, 1901, the new pathological laboratory was opened, and at the opening ceremony Dr. Ritchie, reader in pathology, pointed out that, in addition to giving those who were seeking degrees the opportunities of acquiring the necessary knowledge in pathology, it was the desire of the University to provide opportunities for those who wished after graduation to return to Oxford to prosecute researches in pathology and bacteriology, and to this end there had been provided a special room for experimental pathology. In view of the fact that much of the pathological work of the future must be in the direction of the chemical examination of the products of disease processes, a chemical research laboratory had also been provided.

Already the importance of our new pathological laboratory has been recognised, as a generous donor, Mr. Philip F. Walker, has quite recently endowed a studentship of the [illegible] must devote him- [illegible] ho can doubt that [illegible] tion of much good work, as we all know that many a man eagerly anxious and in every way fitted to carry on investigations of the utmost importance to mankind is prevented from doing so by want of means.

I must not omit to mention that in 1901 the Drapers' Company presented to the University the magnificent medical library which you will find in close proximity to the museum buildings and which will ever remain as a memento of their generosity. In 1902 Mrs. Ogilvie gave to the University a sum of £7000 for the purpose of creating a readership in ophthalmology, to be held by the senior surgeon to the Oxford Eye Hospital, and this readership is now held by the president of the section of ophthalmology, Mr. R. W. Doyne, to whose untiring efforts for many years past we largely owe the excellent eye hospital which now exists in this city.

THE PRESENT STATE OF THE OXFORD MEDICAL SCHOOL.

[illegible] be properly taught. You will find that for many years past adequate provision and suitable accommodation and apparatus have been provided for the teaching of these subjects and that at the present moment they are being taught by professors, readers, and lecturers whose ability and fitness for their important duties cannot be questioned. The Association desired that provision should be made for the elementary teaching of clinical medicine and surgery. In 1883 the existing *Litchfield clinical professorship was split up* into a Litchfield clinical lectureship in medicine and one in surgery and from that date to the present students are taught in the wards of the Radcliffe Infirmary the bare outlines of clinical diagnosis in medicine and surgery and are thus fitted to take immediate advantage of the most advanced teaching and the excellent clinical material they find *awaiting them at the large metropolitan hospitals. Yet it* would appear from the questions so often asked that little is known by the general public of these important changes which have been carried out here during the past quarter *of a century. Less than six years ago* a member of our Association, living not much more than 50 miles from this city, was reported to have used these words in an address he was giving at the opening of a medical school in the West of England, "Oxford still misapplies its medical endowments and declines to reorganise its medical faculty." And again, in the same address, "You must go to either Oxford or Cambridge, where *the demon of athletics reigns* supreme and where professional studies are depreciated if not despised." Had he taken the trouble to inquire he would not have so glaringly displayed his ignorance, for he would have found that medical students at Oxford and Cambridge were as keen and as steady workers as any in the country and that every possible facility and encouragement was being given them for the proper carrying on of their work. A further study of a list of prizes gained and important professional posts held during the last few years by past Oxford and Cambridge students would have proved to him that the time spent at these Universities was not wasted.

[Here Dr. Collier enumerated the makers of the Oxford revival as a medical centre, dwelling at some length on the parts played by Acland, Buckland, Charles Daubeny (professor of chemistry and botany), P. B. Duncan (keeper of the Ashmolean Museum), Robert Walker (reader in experimental philosophy), the fourteenth Earl of Derby (chancellor), Burdon Sanderson, Gotch, and Thomson, and such leading figures in general educational development as the late Dean Liddell and the late Dr. Jowett. He continued:—]

THE INFLUENCE OF THE SCHOOL.

Now let us ask ourselves whether the advantages claimed more than a quarter of a century ago as likely to accrue by associating the Universities of Oxford and Cambridge with medical teaching have in any way been achieved. For some years ago a considerable number of medical graduates have been passing forth into the larger world after spending three or more of the most impressionable years of their lives at one or other of the two Universities. Have they benefited? I cannot for one moment doubt that the majority of these graduates if appealed to would declare with no uncertain voice that they recognised fully that their mixing with men of their own age, who were *taking up other subjects* for their life-work and interesting themselves in other mental pursuits, had done much to widen their own general culture and to develop in them interests outside their own professional work. *Has the University benefited?* I think so. The establishment of the medical school on a modern basis has introduced into the University a body of students starting their university career with a definite object in view and compelled by the very nature of the case to lead a steady, strenuous life, for no student can hope to pass his professional examinations without a due amount of steady work. But to my mind *the greatest advantage to be* noted has been the influence the university student has had on the other medical students of our great metropolitan schools. All of us are familar with the Bob Sawyer type of medical student as depicted by Charles Dickens—*that is to* say, we are familiar with him in fiction—but I rather fancy as a living type he has for many years ceased to exist. Many of us can remember the time when any more than usually disgraceful outbreak of rowdyism in London was invariably attributed, rightly or wrongly, to medical students. But this is a matter of the past. The medical student of a quarter of a century ago undoubtedly bore a very bad character in the eyes of the public; he no longer does so. Why the change? I should attribute it, I believe with truth, largely to the influence of the university graduates who have come among them. These university graduates are older men and have long passed their first experience of freedom from school discipline; have more settled purpose in life, have a clearer and better idea of what is so difficult to define but so easy to recognise—*good and bad form. It is these older students* who, in recent years, have largely dominated the standard of life at our London schools, and their influence has been all for good. Lastly, let me point out that if the standard of general culture is distinctly raised by all the advantages of a university education, as we believe it is, then as the numbers of those participating in this education are increased *the status of the medical profession is certain to be raised.* There are some, I know, who do not wish to see a large *medical school at Oxford. They argue* that the standard should be a high one and only men of quite exceptional ability should be encouraged to seek the Oxford D.M. degree. Surely this is a somewhat selfish and exclusive policy. Everyone would agree that the standard should be high. Some, and I trust most of us, would wish that it should not be too high for the man of average ability with the capacity for work well developed. To such men every encouragement should be given to participate in all the *advantages to be gained by a few years'* experience of university life.

EARLIER BENEFACTORS.

I pass now from Oxford of to-day to Oxford of the past and will recall the names of a few of our greatest men, members of our own profession, who have been associated with the University.

I first mention Linacre, who at the age of 24, in 1484, was elected a Fellow of All Souls and was incorporated a D.M. of the University on his Padua degree. While at Oxford he seems to have devoted most of his time to giving lectures in physic and to the teaching of Greek. Not only was he a profound scholar and a successful physician, but he was also a member of the clerical profession—indeed, the last few years of his life were entirely devoted to clerical work. His wealth was very largely acquired by his numerous ecclesiastical preferments. He bequeathed considerable sums of money to both Oxford and Cambridge for the purpose of encouraging the teachers of medicine, but, unfortunately, owing to the imprudent management by his trustees a good deal of this money was lost. We still have the Linacre Professorship of Comparative Anatomy to remind us of one of our oldest and most distinguished benefactors. It was *mainly due to Linacre's efforts that* the Royal College of Physicians of London was founded in 1518, he being elected the first President. It was probably due to his influence, too, that a statute was passed in Henry VIII.'s reign that no person should practise as a physician or surgeon unless examined and approved by the bishop of the diocese in which he lived, who was to call to his assistance expert persons in the Faculty. This privilege of the bishops continued for a very long period.

For some years Harvey, the discoverer of the circulation of the blood, dwelt at Oxford, where he worked at anatomy and made many dissections. He was incorporated a D.M. of the University and in 1645 by royal mandate was made Warden of Merton College but did not retain the post long, as the following year, after the surrender of the city to the Parliamentarians, he returned to London. It was while *Harvey was at Oxford that another great anatomist* who studied under Harvey was preparing himself for future fame —Thomas Willis, well known to all of us by his description of the anatomy of the brain and more particularly by the circle of Willis. Willis was born of Oxfordshire parents within a few miles of our city and for many years practised his profession in a house opposite Merton College. Associated *with Willis was Christopher* Wren, the architect of St Paul's Cathedral. Born in 1632, Wren left school at the age of 14, and was engaged by Sir Charles Scarburgh to act as his assistant and demonstrator at his lectures on anatomy at Surgeons' Hall, London. Three years later, at the age of 17, he was entered as a fellow-commoner at Wadham, at 21 was made a fellow of All Souls, and at 28 Savilian Professor *of Astronomy. It* was while at All Souls that he made elaborate drawings to illustrate Dr. Willis's work on the anatomy of the brain. In 1679 he made experiments which led him to the invention of a method for the transfusion *of blood from one animal to another.* It was at the age of about 30 he began *to follow* the profession *of* architecture and one of his first works was this Sheldonian Theatre, the first stone of which was laid in 1664 and completed five years later. At the age of nine he was capable of writing an elegant Latin letter to his father but it was science and mathematicians that attracted him. A splendid mathematician, a great experimentalist, always working out the most difficult *scientific problems, a distinguished* astronomer, and a famous architect all combined in one [illegible]

[illegible] years. It was about this period that the Royal Society sprang into existence; largely, as is asserted, by the influence and coöperation of Oxford men. About 1648 Willis, Seth Ward, Robert Boyle, and other members of the University distinguished in theology and science were accustomed to meet in the rooms of Dr. Wilkins the warden of Wadham, [illegible] ority [illegible] ndon [illegible] who [illegible] years he became an undergraduate of University College, ten years later he took his B.M. degree and his D.M. at the age of 32 years. For nine years he practised as a physician in Oxford and we are told that he incurred the anger of the older practitioners in the town because he paid so little regard to professional conventionalities. In 1684 he moved to London and his apothecary tells us that he had scarcely been in town a year before he was earning more than 20 guineas a day. His lively conversation, it was said, soon made him the most popular physician in London. We are told that he succeeded more by his ready wit than his learning, for while at Oxford his library consisted of some phials, a skeleton, and a herbal. In 1692 he lost some £5000 owing to the capture by the French of a ship in which he was interested. When his friends condoled with him he replied that it did not matter, for he had only to go up 250 pairs of stairs to make himself whole again. If this be true the physicians' fees in those days would seem to have been very much higher than at present. At any rate, we can admire his philosophical way of putting up with a financial loss—a little more work will put me right again. If it be true that his witty tongue helped him to succeed in his profession it is also certain that it lost him many influential patients. Early in his London career he gave great offence to the Princess Anne by neglecting to visit her when sent for and by saying that her illness was nothing but [illegible] e should give the [illegible] Later he greatly [illegible] His Majesty, after [illegible] that he would not have the King's two legs for his three kingdoms, a remark so free that the King never saw him again. A few months before his own death he fell into great disgrace because when summoned to attend Queen Anne in her last illness he delayed his visit and was said to have replied that as he understood Her Majesty's case was desperate it would be best to let Her Majesty die as easily as possible. This sounds rather brutal but it was said in reference to the Queen's well-known great antipathy to him and Radcliffe urged that he feared his presence would do more harm than good. In 1695 the King offered him a baronetcy which was declined. We are told that though rough in manner and fond of flattery he was generous to those in need, a good friend, and a munificent patron of learning. He died in 1714 and lies buried in St. Mary's, our University church. Although he was given an almost royal [illegible] the pavement his coffin was discovered, not even a slab marking the spot where he was buried. A simple engraved slab now marks the spot near the north entrance. During his life he gave largely to his old college and to several charities and at his death he left [illegible] to the Masters and Fellows of [illegible] to be held in trust for the found[illegible]ling Fellowships, the overplus being paid for the purpose of buying perpetual advowsons for the college. In addition he left £5000 for the enlargement of the college and £40,000 for the building of a medical library. With money derived from his estates two other buildings were erected in this city by his trustees, the Radcliffe Infirmary and the Radcliffe Astronomical Observatory, and money was further granted towards the building of the Royal College of Phy[illegible] cliffe-square, completed in [illegible] ious buildings in this city [illegible] all of you. It was in this [illegible] Oxford was held in 1835, on your third anniversary. In it you will find a very pleasing portrait of Radcliffe painted by his friend, the King's painter Kneller. I cannot refrain from recording a passage of wit between these good friends. They lived in adjoining houses and for the sake of convenience Kneller had allowed Radcliffe to make a doorway in his garden wall; in course of time this doorway became a source of great annoyance to Kneller, as Radcliffe's servant frequently used it to gain entrance to his garden and to pick the flowers. At last, in a fit of anger, Kneller wrote to Radcliffe, and told him that if he could not control his servants he should be obliged to take the door away and to brick the aperture up. Radcliffe at once sent his servant to Kneller to tell him that he might do what he pleased with the door so long as he did not paint it. Kneller having received the message was equal to the occasion and at once replied, "Go tell Dr. Radcliffe with my services to him that I can take anything from him but physic." Fortunately for Oxford Radcliffe was not happy in his love affairs, for we are told that after passing many years for a misogynist, the result of an early disappointment, he again in his old age fell in love with the daughter of a wealthy citizen, but the match was eventually broken off—a very short time before the appointed wedding day; had it not been we might well have lost our library, our infirmary, and our observatory.

Thomas Sydenham (1624–89), who has always been regarded as one of the chief masters of English medicine, was also connected with the University. His career at Oxford was certainly a chequered one. At the age of 18 years he entered as a fellow commoner at Magdalen; a few months later he joined the Parliamentary forces and fought against the Royalists; four years later, in 1646, when Oxford and the other royal garrisons surrendered, he resigned his commission and was on his way to Oxford when he chanced to meet with Dr. Thomas Coxe who was attending his brother and who persuaded him to take up medicine. He then joined Wadham College and the following year was elected to a fellowship at All Souls. In 1648 he obtained his degree of B.M. in a very irregular manner as he was created B.M. by command of the then Chancellor of the University without having taken a degree in Arts and with little knowledge of medicine. For a time he studied at Oxford under the Regius professor of medicine, whose lectures, we are told, consisted merely in reading the ancient medical classics. Again he joined the army and became a captain of a troop of Parliamentary Horse. On one occasion he was left on the field of battle among the dead and lost, as he tells us, a great deal of blood. On another occasion he nearly lost his life at the hands of a drunken soldier who broke into his bedroom at night and discharged a pistol at his breast. Fortunately the soldier's left hand was interposed and was shattered by the bullet, while Sydenham escaped unhurt. Having again retired from the army he studied medicine at Montpellier and a year or two later began practice in London. In 1676, at the age of 52 years, he incorporated as M.B. at Pembroke College, Cambridge, on his Oxford degree and immediately took the M.D. of that University. It is supposed that there were political reasons for his not taking the Oxford degree. By his methods of studying disease and by his masterly description of diseases Sydenham is admitted to have made an epoch in medical science. In 1894 a life-sized statue of Sydenham was presented to the University museum by Sir Henry Acland and others.

Time will not permit me to mention others who attained [illegible] the [illegible] presidents whose names are recorded, 21 were graduates of the University of Oxford. There are, however, one or two other benefactors whose names I must mention, such as Dr. Mathew Lee of Christ Church, who, after practising some years in Oxford, went to London, became a Fellow of the College and in turn Censor and Harveian Orator; was for some years physician to Frederick Prince of Wales and died [illegible] d in trust [illegible] purpose [illegible] y. Lord [illegible] for the foundation [illegible] ociation with [illegible] he provided [illegible] to visit [illegible] was to [illegible] provided [illegible] was to forfeit a year's stipend to the infirmary and to pay £5 to that institution for each lecture omitted. I am much [illegible] that this most wise stipulation was never really enf[illegible] [illegible] converted into a lectu[illegible] [illegible] Dr. George Aldrich, by his will dated 1803, left a sum of money for the endowment of a professorship of the practice of medicine, which professor[illegible] the very inadequate stipend of the [illegible]

[Dr. Collier then briefly pointed out that the future effi[illegible] [illegible] ies, and concluded by [illegible]

THE PREVIOUS MEETINGS OF THE ASSOCIATION IN OXFORD.

[illegible] Association was founded at Worcester [illegible] arles) [illegible] pro[illegible] [illegible] ted a [illegible] the Association held its first [illegible] presidency of Dr. Kidd; the Council [illegible] arranged all the details of the meeting, which was attended by 300 members. The chief meeting was held in the Radcliffe Camera, the dome-shaped building to which I have alluded, and one or two incidents connected with this meeting are worth recalling. The address in medicine was delivered by Dr. Pritchard and the University conferred on him the degree of M.D. Although this same Dr. Pritchard had studied in Oxford he had been unable to take his degree because he was a Dissenter. The conferment of the degree in this way was taken at the time as a proof that a more liberal spirit was beginning to exist in the University. The Regius professor pointed out tha[illegible] not be procured by any ordinary medi[illegible] than 11 years' classical servitude and [illegible] words, classical servitude, as they imply that even in those days some students did not take kindly to the classics. The chief attraction of the meeting was the public performance of lithotrity by Mr. Costello before a very crowded audience [illegible] anatomy not being sufficiently [illegible] will notice that at that time [illegible] have been thought an unsuitable place for a surgical operation. It was remarked at the time that not a single [illegible] medicine attended to support the Regius [illegible]

Th[illegible] the Association at Oxford, which now [illegible] ers, was held in July, 1852. Dr. Ogle, the Regius professor, was the President, and the meetings, which extended over two days, were held in the House of Convocation. On this occasion the honorary degree of D.C.L. was conferred on three members—Sir Charles Hastings (the founder), Dr. John Forbes of London, and Dr. John Conolly of Hanwell. In the evening of the first day the Association was entertained in the Radcliffe Camera by Dr. Acland.

Another 16 years passed and in 1868 the Association visited Oxford for a third time. It had now grown to a total membership of 3672, of which some 500 attended the meeting. Dr. Acland, the Regius professor, presided, the general meetings being held in the Hall of Christ Church, while the sectional meetings, of which there were five, were held in the University Museum. Among the sectional secretaries on that [illegible] name of W. S. Church, M.A., B.M., n[illegible] e Royal College of Physicians of London, who gives the Address in Medicine to-morrow evening. I am glad to add that the three local secretaries, Dr. E. B. Gray, Dr. H. M. Tuckwell, and Mr. Edward Chapman, now a Member of Parliament, are all living. The [illegible] ferred on the following me[illegible] Rev. Samuel Haughton, M.D., Dr. W. Gull, Mr. James Paget, Mr. John Simon, and Mr. James Syme.

To-day our Association numbers over 19,000 members and we are expecting more than three times the number who visited Oxford in 1868. More than this—and it is, I think, a matter for hearty congratulation—the influence of our Associatio[illegible] branches have been [illegible] ll of our colonies. [illegible] sociation in magnit[illegible] to the fostering [illegible] workers. Into our [illegible] ance and [illegible] unwise and [illegible] way to [illegible] usefulness.

Address in Medicine

ON

"OUR SANITARY NEEDS, WITH SPECIAL REFERENCE TO THE NATIONAL HEALTH."

Delivered at the Annual Meeting of the British Medical Association at Oxford, on July 27th, 1904,

BY SIR WILLIAM SELBY CHURCH, BART., K.C.B., M.D. OXON.,

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON; CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—I feel very deeply the honour which your Council has conferred on me in requesting me to give the Address in Medicine at this meeting of the Association and feel still more deeply the difficulty of the task—a difficulty which arises not only from my own incompetency but also from the vastness and complexity of the subject.

MEDICINE IN 1868.

Medicine having for its object the mental and bodily health of mankind is closely interconnected with the varying circumstances that bear on the conditions under which we live. The prosperity of the nation, the conditions under which the labours of the population are carried on, the state of commerce and of the arts and sciences, all react on the health of the people and nothing which concerns the life of the nation is foreign to the subject. Every advancement in science and its application to the arts has a bearing on medicine. To pure science it is directly indebted for means by which the various organs of the body can be examined, the presence of disease demonstrated, the changes in our bodies accompanying disordered health recognised; and perhaps more important than all, the exact methods of science point out the way in which the more complex questions presented in living bodies should be studied. It would occupy too much time, even if I were competent for the task, to trace a portion of the benefits which the exact sciences have conferred on clinical medicine during the years that have passed since the Association last met in this university city, a meeting at which addresses which still stand out as memorable among the numbers which have been given on similar occasions were delivered by Acland, Rolleston, and Gull, who will for many years yet to come be remembered not only as ornaments of our profession but as having done much to promote medical and scientific knowledge—leaders to whom we can still [illegible] manner in which the different [illegible] hould be approached.

The me[illegible] in 1868 is for another reason of [illegible] as marking the date of [illegible] at period our conceptions [illegible] he body had not undergo[illegible] views held by the origi[illegible] ater, Baillie, Carswell, and of [illegible] nfective processes leading to [illegible] may be said to have been at that time non-existent. The symptoms and course [illegible] which t[illegible] out but [illegible] true nature of the [illegible] progressive, for I find [illegible] matter in the writers on physic.[illegible]

It was in the year preceding the Oxford meeting that

[illegible] Organum, book iv, chapter ii.

ment of compound [illegible] the preceding three [illegible] infectivity of tuberculous matter began generally to be recognised; 20 years before Klencke[4] had produced tuberculosis of the lungs and liver in [illegible] human tubercle, but he did not [illegible] his experiments attracted little [illegible] Villemin's work in 1861[5] and the account of his numerous and careful experiments published in 1868,[6] that attention was again drawn to the subject. Villemin's work was carried on by Sir J. Burdon Sanderson,[7] late Regius [illegible]fessor of medicine in this University, who explored [illegible] erculous pro[illegible] ny years ha[illegible] the presenc[illegible] tuberculous degenerations was essential element.

THE GROWTH OF BACTERIOLOGY.

I have thought it desirable to remind you thus very briefly of the position in which medical knowledge stood in 1868 before drawing your attention to some of the remarks made by Sir William Gull in his address on Clinical Observation in Relation to Medicine in Modern Times, which he treated with the breadth of view and felicity of generalisation which was characteristic of his mind and teaching. It was the adaptation of Pasteur's work and discoveries to medicine and Koch's demonstration of the bacillus of tubercle in 1882 which led to the revolution which has taken place in our conceptions of the nature and cause of many forms of disease. Whilst I have no intention of attempting to review the changes that the last 35 years have witnessed it may be nevertheless instructive, as well as interesting, to turn to some of the passages in Sir William Gull's address and mark how great is the gulf which separates the medicine of the present day from that of our immediate predecessors. In speaking of fevers Sir William Gull[8] said: "In the consideration of these small-pox stands first, since through vaccination we have clearly demonstrated at least for one form of fever—and it seems but fair to infer the same for others—that recovery and subsequent immunity are produced by a process of impregnation and assimilation and not, as is still maintained by some, of elimination"; whilst rejecting the theory of zymosis, by which he says "we are carried back to the days of ignorance when concoction and maturation were made to explain whatever was obscure," he suggests that "what really constitutes the specific character of each fever is the attendant tissue change which, when completed according to the special poison, is followed by convalescence"—although I think it is pretty clear that he contemplated by tissue changes an alteration in the solid tissues of the body, his words do not inaptly apply to the changes which we believe are undergone by the blood. In his Harveian oration delivered two years later he again refers to the subject of infectious diseases, saying: "that they spread by emanations from the sick must have been long known and that such emanations are of a solid nature we may infer from the fact that they may be dried and conveyed from place to place, but in what state, whether as amorphous material or as germs, we know no more to-day than was known a thousand years ago."[9]

How different is the position now. Already we are acquainted with the specific organisms which are the *causa causans* of many of the febrile diseases and can safely assume that the others in which we have not yet discovered the micro-organisms are due to similar agency. How much more hopeful is the outlook now than when Gull said, "It is now universally acknowledged that the art of medicine is all but powerless in controlling the large class of diseases called zymotic. It may be there do not exist nor may ever be formed by art antidotes to their poisons. But should it be otherwise my duty at this moment still seems clear—that I ought not to stir up your minds to search for such secrets of nature. Upon this search too much time has already been wasted and an incalculable amount of life has been lost. Specifics will no doubt continue to be sought after, but preventive medicine will more largely obtain the suffrages of the best informed members of our profession."[10] Truly, as he says in another place, "the knowledge which [illegible] exhaustive to-day may in the changing circum[illegible] of the world be defective to-morrow." For it now [illegible] probable that most if not all of these diseases [illegible] we already know of some [illegible] te, and that as Sir John [illegible] ous substance which is ca[illegible] the [illegible] able of [illegible] first."[11] [illegible] he most [illegible] and the [illegible] dal, and [illegible] properties of the blood serum under certain conditions. The investigations which have been so actively carried on in recent years in these directions have greatly increased our knowledge of the blood and its component parts and we trust that they may lead to still further advances in the field of serum therapeusis—a field which offers a hopeful prospect for enabling us to counteract the bad effects to which specific disease-producing organisms are capable of giving rise in the living body.

INTERNAL SECRETIONS.

Another most important step onwards in our physiological knowledge and its application to the treatment of disease was made when we became acquainted with the connexion existing between that group of symptoms which we now call myxœdema and disease of the thyroid gland. Sir William Gull himself, in 1873, was the first to draw our attention to the cretinoid state supervening after adult age,[12] but it was from the researches of Ord, Reverdin, Kocher, Horsley, and Murray that the existence of what are spoken of as internal secretions of glands was suspected and proved.

The brilliant results from the administration of the thyroid gland or its extract in myxœdema raised our hopes and expectations that we might, by the administration of other glandular extracts, obtain benefit in those morbid conditions in which it appeared probable that an internal secretion bears a part. As yet these expectations can hardly be said to have been fulfilled. Neither in diabetes nor in morbus Addisonii has the administration of the pancreas or the suprarenal glands been followed by any marked or constant beneficial effect on the disease. The researches of Schäfer and Oliver have proved the [illegible] the suprarenal glands [illegible] and further researches [illegible] the physiological func[illegible] able us to make therapeutic use of them. Hitherto we have used these glandular extracts to supply the place of the normal secretions which we have inferred might be absent owing to disease being present in the secreting organ. Is it not possible—nay, probable—that it is not this simple absence but rather the presence of a vitiated secretion acting prejudicially on the organism which produces the evil with which we have to contend?

Further observations by Dr. G. Oliver[13] show the remarkable effects which are produced on the blood pressure by the administration of small doses of creatinin, uric acid and its compounds, glycogen, xanthin, and the purin bodies contained in food; while equally active depressors of arterial pressure are found in bodies so closely allied by chemical composition to those which increase it, as are creatin, hippuric acid, and hypoxanthin.

TROPICAL MEDICINE.

In other lines of research the progress made is not less remarkable. The ancients were well acquainted with the commoner forms of intestinal worms, although they were ignorant of the remarkable phases presented in their development. They have left us full and accurate descriptions of the clinical symptoms produced by them and the means which should be adopted for their cure.[14] Until a very few years ago we could hardly be said to possess more knowledge than our predecessors of the part played by the animal

kingdom in the dissemination and propagation of disease in man. It had long been [illegible] shared with animals the liability to [illegible] maladies—for example, rabies and [illegible]ion existed of the important part which the lower orders of creation play in the maintenance and diffusion of some of the most widespread and deadly of the diseases which affect man.

Slowly and gradually the natural history of malaria and yellow fever has been worked out. M. Laveran, in 1880, first discovered and described the organism of paludism in the blood, and his discovery, like that of the tubercle bacillus by Koch in 1882, forms an epoch in the history of medicine. Laveran's observations were carried on by many others, of whom I must mention Marchiafava, Bignami, Celli, and Golgi, who, together with many other distinguished Italian *savants*, did so much to make us acquainted with one portion of the life-history of the malarial parasite, many years before its complete life-cycle had been discovered by the suggestions and reasoning of Manson and the laborious and persevering investigations of Ross. Already the work done, mainly under the auspices of the Liverpool and London Schools of Tropical Medicine, has begun to bear fruit not merely by increasing our knowledge of malaria and certain other forms of tropical disease but by having in the short space that has elapsed had a marked influence in diminishing sickness and mortality in places which were so deadly to European life that trade could hardly be maintained with them. Nor is it only in these hotbeds of fever that beneficial results have been obtained, as Professor R. Boyce's account of antimalarial measures taken at Ismailia shows. The result of the sanitary work put in action by the authorities of the Suez Canal has been eminently satisfactory. The attacks of malaria in a population consisting of about 1900 or 2000 Europeans and 7000 natives have fallen from 2089 in 1897 to 209 in 1903 and the mortality has correspondingly lessened. These highly satisfactory results have been obtained at comparatively small expense, the Canal Company having expended £4400 in filling up and draining the marshy ground whilst the special antimalarial forces—the drainage and the petroleum brigades—have together cost £720 a year, figures which contrast most strikingly with a previous "expenditure of £15,000 on works designed with the intention of improving the sanitary condition of the town and £13,000 in medicine and medical attendance,"[15] without the production of any beneficial results.

The mystery surrounding the sleeping sickness of Africa has been partially dissipated by the discoveries of Castellani, Bruce, and Nabarro and the remarkable life-cycle of the trypanosoma is in a measure unravelled. A similar chain of events appears to occur in Texas fever and probably in other morbid states the lower forms of animal life play a much more important rôle than is yet recognised. Recent investigations by Leishman, Donovan, Ross, and Christophers tend to show that the condition of chronically enlarged spleen and cachexia which we have been accustomed to ascribe to malaria is more probably dependent on another distinct micro-organism.

Interesting as is the connexion which we now know exists between the lower forms of life and the presence of disease in man I must not occupy your time by further reference to it and I must pass by the additions to our knowledge of the nervous system and its disorders, of the blood, and of the application of electricity in its various forms to the diagnosis and treatment of injuries and disease, for it is not my intention to attempt to review the progress of medicine during the years that have elapsed since the Association last met in this place.

THE PRINCIPLES OF PREVENTIVE MEDICINE.

It appears desirable that I should remind you thus briefly of some of the more striking changes which have taken place in our conceptions of diseases, their causes, effects, and our means of opposing them, for events crowd so rapidly on our notice in these days that we are apt to forget how short a time has elapsed since the veil was raised and we began to see—dimly it may be—the connexions which exist in disease as well as in health between man and his surroundings. Herbert Spencer's "environment" and Darwin's "survival of the fittest" depend to a great degree on forces which when these phrases were first made use of were not present to the minds of their inventors.

The exact knowledge, based on scientific research and demonstration, which we now possess of the cause and nature of disease has greater influence on preventive or State medicine than on clinical treatment. Recognising the sources of our ills we are in a position to avoid and to guard ourselves against them. To the general public the advances made are most palpable in the triumphs of modern surgery, which is in some danger of being led into excesses by the impunity with which operative measures can now be undertaken. This knowledge of facts in the place of the theories of former days leads me on to a consideration of the position in which medicine has stood in the past and that which it should now hold in relation to the public and the State.

IN GREECE AND ROME.

It is to be regretted that we know so little of the position which the practitioners of medicine held in the State in the Greek and Roman worlds. In Greece, at the period of its highest intellectual activity, we know from the references made to physicians by Plato and others that they were men of learning and possessed of considerable influence. From Plato also we learn that there were two or more distinct classes or grades of practitioners, for in the Laws the Athenian asks Cleinias: "You are aware that there are two classes of doctors?" Cleinias: "Yes, and did you ever observe that there are two classes of patients in States—slaves and freemen; and the slave doctors run about and cure the slaves or wait for them in the dispensaries ......, but the other doctor, who is a freeman, attends and practises on freemen?" and the Athenian stranger goes on to describe the differences in the mode of practice of these two classes of doctors.[16]

From this passage also we learn that the Greek cities at that time possessed dispensaries—*ἰατρεῖα*—places where the slaves and probably the poorer citizens were wont to consult the doctors. From another passage in the Gorgias it appears that in the Greek cities there existed medical officers who were appointed by the municipality, for when speaking of the power of rhetoric Gorgias says "that if a rhetorician and a physician were to go to any city and had there to argue in the ecclesia or any public ceremony which of them should be elected State physicians the physician would have no chance." Socrates: "You were saying, in fact, that the rhetorician will have greater powers of persuasion than the physician even in a matter of health." Gorgias: "Yes, with the multitude." Socrates: "You mean with the ignorant."[17] I fear we know to our cost that in matters of health the rhetorician and the politician is still not infrequently of more influence with the multitude than the physician.

Very little is known of the position of medical practitioners in Rome during republican times. The wealthier Roman families appear to have kept in their retinues slaves or freedmen who had received some instruction in medicine and surgery, most probably in some of the Greek colonies in Italy, but in Imperial Rome we know that in medicine the larger cities possessed some municipal organisation similar to, if not identical with, that which had been in force in earlier Greek times. Before the time of Antoninus Pius (A.D. 136) recognised medical practitioners were exempt from ordinary civil obligations and local taxation but their numbers had so largely increased by this time that it became necessary to limit the number of recognised practitioners in each city who should enjoy this immunity; and Pliny, who seems to have had nearly as bad an opinion of our profession as Cato, complains that the law unduly safeguarded physicians and that they alone could kill a man with impunity.[18]

The disorganisation which after the fall of Rome affected every community in Western Europe envelops the subsequent position of medicine in obscurity. During these unsettled times the doctors appear to have been attached to persons rather than to communities; and this condition prevailed to a greater or less extent until comparatively recent times, and is even now perpetuated in the honorary posts attached to the royal families.

Time does not permit me to sketch, however briefly, the steps by which in this country the mediæval guilds of barbers, barber-surgeons, and surgeons became gradually developed into the surgeons of to-day.[19] The better regulation of the profession in this country may be said to date from the institution of the Royal College of Physicians in 1518, which was intrusted with the general supervision of all persons not graduates of the two English Universities of [illegible] practise physic through- [illegible] a charter by Henry VIII. [illegible]

THE BRITISH MEDICAL ASSOCIATION AND MEDICAL LEGISLATION.

Sir John Simon in his most interesting work on English sanitary institutions[20] has a chapter entitled "Growth of Humanity in British Politics." In it he traces the influence of the religious revivalism under the Wesleys and the noble work of Howard in arousing among the better-informed classes a humanitarian spirit which has been one of the many factors, and perhaps the most powerful, which led to the reformation of the criminal code, the abolition of slavery, and the Factory and Sanitary Acts of the nineteenth century. During the earlier part of the nineteenth century it was gradually brought to the attention of thoughtful men that steps should be taken to regulate the education and the practice of medical men. The first result was the passing of the Anatomy Act in 1832, which was followed by the appointment in 1834 of a committee of the House of Commons to inquire into "the laws and usages regarding the education and practice of the various parts of the medical profession in the United Kingdom." No report was presented by this committee although it took a great deal of evidence; part—that relating to Scotland and Ireland—was never printed and is supposed to have perished when the Houses of Parliament were burnt. Mr. Warburton, who acted as chairman of the committee, introduced in 1840 a Bill into the House for the registration of medical practitioners but found little support. Sir James Graham and Mr. Manners Sutton prepared and brought in a Bill, four years later, "for the better regulation of medical practice throughout the United Kingdom." The Government of the day declined to interest itself in the Bill, and no further action took place until this association—then called the Provincial Medical and Surgical Association—under the leadership of Sir Charles Hastings, brought the subject under the consideration of Lord Palmerston in 1853, and of Sir G. Grey in 1855, in the hope that the Government would promote the Bill which the association had prepared. Neither Minister would undertake to bring it in as a Government measure, and a private member—Mr. Headlam, M.P. for Newcastle—in 1855, and again in 1856, introduced a measure which represented the views of the association. By the influence of Mr. Cowper, then President of the Board of Health, the House of Commons referred the Bill to a select committee—a proceeding which eventually resulted in the Medical Act of 1858, which has been productive of incalculable benefit both to medical education and to the public. This association may well take pride in remembering that this was accomplished mainly through its influence and action.

POOR-LAW AND PUBLIC HEALTH LEGISLATION.

Contemporaneously with the awakening of public opinion to the necessity for a reform in the constitution of the medical profession by which the public might be able to discriminate between those who were and those who were not legally qualified to practise, the need for increased legislative power for sanitary purposes was recognised. The public mind had been aroused by the ravages of cholera which spread through the land in 1831–32 and to a less degree in 1848–49; whilst the revelations of the conditions under which the labouring poor [illegible] reports of Dr. Neil Arnott, Dr. [illegible] Mr. Chadwick, and others to [illegible] appealed to all but the most thoughtless and prepared the way for sanitary legislation.

I am not forgetful that from the earliest periods of civilisation it has been recognised that large centres of population have necessitated laws and regulations for the prevention of nuisances and the removal of refuse. These were among the most important duties of the ædiles in Rome, and in the records of mediæval London are constant references to the removal of nuisances, the cleansing of the streets, and the necessity [illegible] that is increasing in the river ar[illegible] ames to the great abomination ar[illegible]

The dissolution of the monasteries and other religious foundations in the sixteenth century led to the whole country being flooded with pauperism, for however self-indulgent the ecclesiastics may have been they had always exercised supervision over the poor on their estates, and administered relief as required to those who were in the employment of the religious houses or of their numerous tenants. This deplorable condition of the nation gave rise in the early years of Elizabeth's reign to our present Poor-law, and during her reign and that of her immediate successors very stringent Acts of Parliament and municipal regulations were passed not only for the removal and prevention of nuisances but also dealing with vagrancy and mendicity and provision for the relief of pauperism and the care of the impotent poor. From that time onward numerous local Acts on a variety of subjects bearing on the national health were added to the statutes but no comprehensive scheme was instituted until we come down to the Victorian Era, and the passing of the Public Health Act of 1848 may be taken as the date of the rise of a fresh branch of medicine—preventive or State medicine.

It was then that the State publicly recognised what Hobbes 200 years before, when writing of the "Commonwealth," had indicated as the function of the governing power.

[illegible]

The health of the people, both bodily and mental, is the principal asset of the nation. Without a vigorous and energetic population no nation can make progress and coincident with the cessation of progress is the commencement of decadence. We have heard of late very much about the deterioration and degeneration of our population. I cannot venture to express an opinion on such a complex and difficult subject but I can safely say that there exist no standards by which our present can be compared with our past condition and I greatly doubt if those who talk and write so volubly on the subject are acquainted with the reports made to the Poor-law Commissioners 60 years ago. The present state of our population is serious enough, and it behoves us all, medical men and laymen alike, to do what we can to ameliorate, if we cannot remove, the conditions which militate against the health and happiness of the population.

Steam and electricity have revolutionised the world and the conditions of modern life are now entirely different from those prevailing during the first decades of the last century. The food, clothing, housing, and circumstances in which large numbers of our population work are very different now in both our rural and urban populations from what they were then. Are the changes calculated to benefit the physical and mental condition of the people? or have all our boasted improvements proved snares and delusions? These questions are fraught with the greatest importance to the nation, questions which in the absence of any known standards for comparison with the past it is difficult, if not impossible, to answer. I trust that the committee of the Privy Council on the physical disability of recruits now engaged in framing its report may urge on the Government the desirability for a physical census of the nation being taken and renewed from time to time and that the physical condition of the children in our primary schools should be watched, recorded, and reported on as regularly and carefully as their educational progress. It is only by information of this sort, collected by competent persons and duly weighed by those capable of forming an opinion on the medical aspects of the question, that improvement can be hoped for.

THE CODIFICATION OF PUBLIC HEALTH LAW.

I have already alluded to the Public Health Act of 1848 as marking the introduction of preventive or State medicine. Since that date numerous royal and other commissions have been engaged in the investigation of a very large number of subjects bearing on the national health, with the result that from that time to the present the legislature has been continually occupied in passing new measures for the furtherance of health or the amending of old ones.[23]

---

[19] For much interesting information on these points, vide South's Craft of Surgery, and papers by D'Arcy Power, F.R.C.S., in the Medical Magazine, 1899.

[20] 1890.

[21] Order of Edward III., 1357, vide Sir J. Simon, p. 40.

[22] Hobbes's Leviathan, chapter xxx.

A certain amount of consolidation of the sanitary law was effected by the Act of 1875 but the mass of sanitary legislation and the involved nature of it prevent the public, and I might say the profession also, from being able to follow it. Its complexity in part arises from different departments of the central government being responsible for the means which are taken for safeguarding the public health.

Legislation at the present time appears to me to be in advance of administration and it is not so much fresh legislation that is needed as the simplification and codification of the existing law. The administration of the law cannot be much in advance of the knowledge and feeling of the public and while giving full credit to municipal and other sanitary authorities for the good work already done and the efforts they are now making, the medical officers of health throughout the country are painfully aware how great is the ignorance shown by the mass of the population of the principles on which the public health depends and how great is the necessity for educating the general public to a proper appreciation of the elemental facts of sanitary science.

The all-important part that micro-organisms play in the putrefaction and decomposition of organic matter and in the production of disease was unknown when sanitation first seriously occupied the attention of the legislature. The air, the earth, and the waters all teem with them; and although we recognise in some our deadliest foes we must not forget that it is due to the beneficent action in their countless millions of other members of this group that we mainly owe both the purification of the water we use and the earth we live on; if it were not for their action we should be smothered by our own refuse. As a consequence, this increase of knowledge has rendered it necessary for those who hold important positions in connexion with preventive medicine to have special preparation for their work. The need for this was foreseen by Sir Henry Acland who, in his address, remarks that:

> The Government will have to define the duties to be discharged by public health officers or other officers of public medicine and the General Council of Medical Education will be able to direct the education of those who aspire to the performance of the duties so defined.

The General Medical Council and the educating bodies have fully acted up to this expectation of Sir Henry Acland and the universities and diploma-granting corporations have established special courses of instruction and special examinations requiring a very high standard of professional knowledge from those who desire to qualify themselves for holding responsible posts in preventive or State medicine, which is now justly regarded as the highest branch of our art.

Does the large body of highly qualified officers of health and do the medical officers of the Local Government Board possess the influence in the Government and in the country which they ought to own? I fear not; neither in the Government nor in the country do they hold the position which they are entitled from their high qualifications and the importance of their duties to command. Your President last year directed your attention to the need for reform both in the central authority—that is, the Local Government Board—and in the local authorities.

THE INEPTITUDE OF THE TREASURY REPORT.

During the past year your council and its medico-political and public health committees have been engaged in framing a Bill which it was hoped might be brought before the consideration of the Government. I am afraid from the nature of the report of the Treasury Committee appointed to consider the position and duties of the Board of Trade and the Local Government Board there is not much prospect of the importance of the Public Health Department of the Board receiving any increase either of power or payment. The health of the nation, on which its success and prosperity depend, is thrust into the background with the remark that the President of the Board "has the advantage not only of the medical officer of the Board but also of the general administrative experience of the permanent secretary." In an article in the *Times* of June 14th last upon the report the writer remarks: "The commercial community cannot hope to exercise the influence due to its position in national life so long as its official representative is treated as of second-rate importance." These words appear to me to apply with even greater force to the Department of Public Health in the Local Government Board.

THE DUTIES OF THE LOCAL GOVERNMENT BOARD AND MEDICAL OFFICERS OF HEALTH.

I do not think that there would be any advantage in my dwelling on the terms of the Bill which your Council proposed but there are certain points in connexion with it that should be continually pressed upon the attention of the President of the Local Government Board and the Government:

1. That whilst the administration of sanitary legislation must be left to the local authorities the central authority should act as an advisory as well as a supervising authority.
2. That both in the Local Government Board and in the local authorities the medical element should have greater weight and authority than at present and that the medical officers of health throughout the country should be responsible to the Local Government Board as well as to the local authority and hold their office during the pleasure of the Local Government Board and not at the will of the local authorities.
3. That steps should be taken by which the medical officers of health and the Local Government Board, which at present is the department mainly charged with supervising the administration of the Sale of Food and Drugs Acts, should undertake further duties of supervision and watchfulness in relation to the purity and wholesomeness of articles sold for food.

NEED FOR SUPERVISION OF THE SALE OF FOODS.

The need for such increased supervision was forcibly brought to the attention of the commissioners appointed to inquire into arsenical poisoning. At the present moment there are no means by which the officers, medical or other, of county, borough, urban, or district councils who are responsible for the local administration of the Acts relating to the sale of food can enter the premises and obtain information concerning the nature of food-stuffs or the process of their manufacture. At present the maker of food-stuffs sold under a fancy name is under no obligation to submit to any authority the composition of its ingredients. It is only after the food-stuff has been placed on the market that any control can be exercised by samples being taken for analysis, which, although showing the absence or presence of deleterious matter, gives but little guide to the suitability and value of the preparation as a food. The enormous bulk of these fancy and largely advertised foods on the market, both home-made and imported, renders it essential that further power in the supervision of food should be placed in the hands of the health authority.

RURAL HYGIENE

The necessity for sanitary regulations being so much greater in large towns with their dense populations, manufactures, and difficulty in disposing of their refuse naturally led to the earlier efforts in the direction of improved sanitation being especially directed to their most urgent needs, and hence it has arisen that the methods of sanitation applicable to large towns have been accepted by the public as the only ones and are imitated in rural districts to the great loss and harm of the community.[24] It is greatly to be regretted that Mr. Chadwick's doctrine that not only domestic sewage but all sorts of refuse are best removed by the scour of running water has received such general adoption. Whilst the advantage of the present [illegible] which although ruinously expensive is [illegible] our large towns and must perhaps [illegible] t in accordance with common sense that it should be recklessly applied throughout the country. The disposal of the liquid sewage, not only of our large towns but of our villages, villa residences, and country-gentlemen's [illegible] has become a most difficult problem for modern [illegible]

[24] [illegible] G. Vivian Poore, M.D., [illegible]

"In rural and [illegible]
more to ask othe [illegible]
feed him or clotl [illegible]
of the individu [illegible]

[illegible] system of sewerage necessitates a constant water-supply far in excess of the needs of the inhabitants for domestic use; it introduces a source of danger of pollution for the springs and wells of the locality, and renders necessary the introduction of waterworks to supply uncontaminated water—if, haply, such can be found—brought, it may be, from a distance, and entails a heavy and permanent charge on the locality. The interest of the money thus spent would in many instances provide for the necessary expenses which a proper system of scavenging would entail.

URBAN HYGIENE.

Is the Local Government Board, and are our urban and rural sanitary authorities, really guided by their sanitary officers in these matters? It is hard to believe it, for one sees around one in the metropolis and in our provincial towns and rural districts numberless instances of divergence from the principles of sanitary science. The enormous value of land in London and our large cities has led to a remarkable change in the character of their buildings. At the very time that it has become generally recognised that fresh and moving air is one of the necessities for healthy life and whilst vast sums are being paid for securing open spaces and widening streets the private speculator is allowed to erect huge piles of bricks and mortar which effectually block the currents of air which are required to freshen and vitalise the atmo [illegible]
and thickly populated courts. [illegible]
ance with our present knowledg [illegible]
architects understood much better the principles necessary
for healthy life; [illegible] those
around us here. [illegible] acious
quadrangles freel [illegible] unded
by sets of rooms [illegible] the air
on both sides and seldom more than three storeys in height. The greatest enemies that the disease-producing microbes have are air and sunlight—some of them are deprived of vitality and their power of evil by a few hours' exposure to sunlight. What chance has the microbe of meeting these conditions in the piles of brick and mortar which are now built around central wells, into which a few rays of daylight struggle by means of glazed tiles and to which the purifying and cleansing action of a brisk wind can never reach?

We see equally regrettable proceedings, although of a very different kind, going on in the outskirts of London and our large provincial towns and I regret to say in many of our rural villages. Rows and rows of houses—what are often termed "workmen's houses"—are erected on the plan of
[illegible] und them, no
[illegible] the sanitary
[illegible] between them
[illegible] authorities in
their by-laws have based them on ones which may be applicable to London but are calculated in suburban and rural districts to reproduce all the evils of the town. Sewers and waterworks are provided at the expense of the district, not for the benefit and advantage of the inhabitants,
[illegible] rden ground and space
[illegible] landowner and builder
[illegible] ground-surface at their
[illegible] of
nation.

In the decennial supplement to the
report for 1895, Table R shows that t
in England and Wales is in proportion t
population, the districts most densely
[illegible] great

[illegible] ortality is by
[illegible] a measure of
[illegible] of Tables S
[illegible] eral's report shows how excessive
[illegible] "Urban England." Taking the
[illegible] e infantile mortality of the whole
[illegible] 1000 births for males under one
[illegible] ery 1000 births for females of the
[illegible] rate being 180 for males and 149
[illegible] r "Rural England" being 136 and
[illegible] respectively. Table Q shows the same in a still more striking manner; the agricultural counties of Herts, Huntingdon, Wilts, and Westmorland, in which there are no large towns and no crowded industries, stand lowest with an infantile mortality not exceeding 100, whilst Northumberland (182), Durham and Lancashire (179), and Nottingham (172) have the highest infantile mortality of all our counties, London (149) and Middlesex (130) holding intermediate positions. Other factors besides density of population undoubtedly have a share in producing these results; but there can be no doubt that density of population is one of, if not the, most important of the causes producing this deplorable sacrifice of life.

Very interesting figures are given by Dr. J. F. J. Sykes in his Milroy lectures, 1901, showing that whilst the general and infant mortality in the Peabody and model buildings in St. Giles's is much below that of London generally, as would be expected from the class of persons inhabiting them and the supervision to which they are subjected, the death-rate from certain infectious diseases was in excess of that of London, demonstrating the risk which is run by aggregating, even under favourable conditions, a large population under what may be considered one roof.

The phrase "back to the land" has of late been much in the mouths of many would-be philanthropists and politicians and much has been written on this theme in the ephemeral literature of the day. I fear that as a remedy for physical deterioration or agricultural depression it must be regarded as utopian; even the powers of the legislature cannot prevent the course of economic laws from taking effect but the legislature might, I venture to think, do much which would aid in preventing the continual growth of known and acknowledged evils. It is the province of the legislature, as Hobbes said, to procure the safety of the community even if it interferes with the freedom of individual action; it is done every day in connexion with infectious disorders and with the approval of the public. Our sanitary authorities, guided as they now should be, not by theories of disease, but by facts capable of scientific demonstration, should have the power to restrain both individuals and public bodies from perpetuating and increasing evils which threaten materially to injure our welfare and prosperity as a nation. Overcrowding, whether of houses or localities, should be more stringently dealt with;
[illegible] of certain trades
[illegible] nd public money
[illegible]
congestion of our central districts, whereas they might be used for the opposite purpose and enable many of our trades and much of our business to be carried on outside the limits of our towns. Rural sanitary authorities should be taught to shun instead of imitating those methods of sanitation
[illegible] so costly, so difficult

[illegible] n able to bring before
[illegible] h in a manner worthy
of yourself, this great audience, and the subject; it is one of supreme importance, far transcending the ordinary political issues of the day. I have endeavoured to point out the need

[illegible]

the country and the empire depends.

[13] Poore, Rural Hygiene, third edition, p. 213.

leprous parents are not leprous and if early separated from their parents rarely become so. To save the children it would seem as urgent, as in the case of children born of tuberculous parents or even more so, to remove them at once from their unhealthy surroundings to a district free from leprosy. I cannot end my remarks on this disease without paying a tribute to the highly scientific investigations of this scourge by my old friend and pupil, the late Dr. Beavan Neave Rake, who fell a martyr to this horrible malady as the result of devoting his life to the alleviation of the sufferings caused by it among the natives of Trinidad.

After what I have said of leprosy I need scarcely more than allude to malaria, which in lectures delivered before the Royal College of Surgeons in 1884 was described as a climatic diathesis. The protozoon was discovered by Laveran in 1880 and its life-history has since then been worked out—its inoculation after sunset by the night-feeding anopheles and its destruction by quinine. Its heredity therefore need not be discussed but the effects of malaria in infancy and childhood are most injurious, not only on growth and development but especially on the mental faculties of the child. Protection by avoidance of exposure after sunset and by quinine and early removal to a non-malarious district should be insisted on for the healthy rearing of children born in malarious districts. With tubercle, leprosy, and malaria taken out of the diatheses and hereditary disorders by the discovery of their respective parasites and classed under infective diseases the belief in general hereditary diseases has been very much shaken.

We pass now to the consideration of a disease which we know can be transmitted by either parent to the offspring during the active stage of the disease. I allude to syphilis. From one generation to the next it passes, but beyond that transmission is very doubtful. I doubt whether a disease propagated only so far deserves the name *hereditary* and I am inclined to suggest that the term *transmitted syphilis* far more correctly expresses our knowledge of this disease in childhood than the term *hereditary syphilis* which is commonly employed. This disease, so aptly described by the late Dr. W. Moxon as a "fever diluted with time," becomes transmissible owing to its lengthened period of activity, but the exact process of transmission will remain obscure and to some extent theoretical until the actual organism causing the fever, be it protozoon or bacillus, is discovered. At present we only know it by its effects. Mr. J. Hutchinson, whose clinical researches in this disease cannot be too highly praised, regards the disease as capable of being carried by either the sperm or germ cell to the fœtus or by the mother to a healthy fœtus if she be infected during her pregnancy. What is certain is that if both parents suffer severely from the disease the results to the offspring are doubly disastrous. I have notes of a case of this kind in which the first eight conceptions ended either in miscarriage, premature births, or the births of children that only survived a short period, and it was not till the ninth that a child was born with sufficient vitality to live through the first two years.

In criticising the term *hereditary* in its relation to infantile syphilis I mentioned that it was doubtful if the disease could be transmitted to a third generation. I have notes of only one case bearing on this subject, but it is a very striking one. A blind man met a blind girl at a school for the blind and they married. They were both characteristic specimens of transmitted syphilis, having notched teeth, opaque corneæ, square heads, and scarred mouths. The man was admitted under my care for syphilitic bone disease and hearing that his wife had an infant two months old I sent for it. The child was not a fine one but she was quite healthy and during the time I watched her, more than a year, she showed no signs of transmitted disease. Mr. Hutchinson says that about eight cases have come under his observation in which persons undoubtedly the subjects of inherited disease have become parents. With one doubtful exception he had never been able to discover any evidence of disease in the offspring.

Syphilis is a disease over which drugs exert a powerful controlling influence and under favourable surroundings and good diet it tends to wear itself out. In comparing syphilitic with tuberculous families it will generally be found that the later children of syphilitic parents are the most robust, whilst the elder children of phthisics, that is those farthest removed from the later stages of the disease in the parents, are the most healthy. Syphilis although apparently not transmitted as an active disease to the third generation nevertheless has such an effect on the developing infants of the second generation as to lower their general physical type, which is shown in stunted growth, flattened bridge of the nose, imperfect teeth, coarse skin, and general defective development. The new type thus formed will have a tendency to be transmitted and by intermarriage to be rendered more permanent and this disease thus becomes one of the causes of physical degeneration in large cities.

Another disease more especially occurring in large towns and responsible but to a less extent than syphilis for physical degeneration is rickets. So far as our present knowledge carries us this is a purely dietetic disease but it can be transmitted both as a tendency and as a type. It can be produced in any child by withholding proper nourishment and substituting an innutritious diet. Ignorant artificial feeding lays the foundations of rickets which first shows itself in the over-distended abdomen, perspirations, capricious appetite, and irregular bowels, then follow the enlarged epiphyses, the bending of bones, the softened ligaments, large head and widening between the eyes, beaded ribs, and L-shaped thoracic depressions. It is a common disease in underfed puppies and by breeding from rachitic types the dachshund has been specialised with its large head, long body, short bent leg and thigh bones, and splay feet. The most approved type of field spaniel seen at dog shows is also a good specimen of hereditary rickets. The general effect of rickets is to enlarge the head and shorten the stature. So long ago as 1881 in a discussion at the Pathological Society I suggested that it might be justifiable to induce rickets artificially in microcephalic idiots and small-headed infants with a view of giving more room for the brain to develop. I think it may be said that persons who have recovered from rickets and have afterwards been well nourished often show great capacity for learning, so that this disease offers some compensation in greater skull capacity for the inconvenience of bow legs or knock knees, all of which may be corrected by surgical treatment. But a child that has been the subject of rickets never attains to what should have been his proper height.

The two diseases, syphilis and rickets, the one dependent on uncontrolled vice and the other on injudicious or insufficient feeding and bad air, are the chief causes of the stunted growth and weak physical development of the lower orders in large towns. We have only to watch an organised demonstration of those out of work march through the streets of London to have brought home to us the wretched specimens of humanity reared in the slums and alleys of this great metropolis. Their poverty is seen to be obviously due to incapacity, their incapacity to defective development, and their defective development to moral and physical degradation. Every encouragement should therefore be given to those societies whose work it is to rescue children from the pernicious and unhealthy surroundings of towns and bring them up in the fresh air of the country.

Rheumatism is another disease or group of diseases which has been ranked as a diathesis and regarded as hereditary. Some believed rheumatic fever, rheumatoid arthritis, and gout to be simply phases of the same diathesis at different periods of life. Others with clearer insight recognised two distinct diatheses, a rheumatic and a gouty. But rheumatic fever runs a course with definite symptoms like an acute specific fever and now that a diplococcus has been found in the rheumatic nodules, joints, and vegetation on the valves, which can be cultivated and be used to reproduce the disease in the lower animals, this disease will soon be classed with other specific fevers and the idea of its being hereditary will disappear. There seems, indeed, to be evidence of "rheumatism houses" as there are "tubercle houses" and "cancer houses," probably low-lying badly-drained places where such organisms as cause the diseases once introduced continue to flourish. I am inclined to think that the history of joint diseases will soon have to be rewritten entirely and the so-called rheumatisms will be classified as inflammations of joints dependent upon this or that organism. We already know that the gonococcus whether introduced through the conjunctivæ or urethra may cause a specific inflammation of a joint in which the coccus can be traced. We know that the pneumococcus, bacillus coli, streptococcus, and staphylococcus may all attack the synovial membranes, and probably there are others as yet undistinguished which induce special inflammations.

When we come to gout we recognise another dietetic disease similar to, or rather the antithesis of, rickets. Gout like rickets can be produced in a single generation and again like rickets it shows a te[illegible] ing generations. Ricket[illegible] infants, gout by the [illegible] addition of fermented li[illegible] of gout, which is said to exist in three-fourths of the families of the leisured class, it is necessary to remember that the children are brought up as a rule in the same affluent circumstances as their parents and are early taught to live in the same way. The type of man usually regarded as gouty is illustrated by the John Bull of *Punch*—a plethoric, heavy, genial, but somewhat irascible individual, with a very good opinion of himself, but the type does not always breed true, for there are many thin, wizened, little old men who are martyrs to gout.

[illegible] the so-called diatheses and [illegible] one finds that modern [illegible] the views formerly held as [illegible] supposed to exert in the causation of disease. Tubercle, leprosy, malaria, and I think I may say rheumatic fever, are all infective diseases the micro-organisms of which are recognised. Syphilis when active may be transmitted to the second generation, but there its influence as such probably ceases. Rickets and gout, the two dietetic diseases, [illegible] to carry their effects [illegible] deposit is the sole surv[illegible] But there may be yet [illegible] may be that this is not a mere crystallising out of a supersaturated solution of the salt from the synovia, for if so all joints ought to suffer alike. Perhaps it may be shown that a particular micro-organism is favoured by the presence of a highly nitrogenous and alcoholic medium and is the cause of the precipitation; and that in rickets the mal-assimilation may favour the growth of another organism the presence or the toxin of which may cause the changes in the bones and epiphyses characteristic of that disease.

I ought perhaps to make a few remarks on cancer which, in spite of the strong evidence of its local origin, many have thought to be a hereditary disease. The late Sir James Paget strongly believed in its hereditary character yet was only able to discover a trace of the family history in one in three of his private patients and in one in five or six among hospital patients. John Birkett always maintained that it was much more common to find cancer commencing in a person who had no family history of cancer than in one who had, and Cripps showed that the proportion of deaths from cancer among parents and grandparents of cancerous patients was scarcely larger than the proportion of deaths from cancer to deaths from all other causes. Evidence seems to be accumulating that we are dealing with a disease that in certain circumstances is contagious and inoculable in the same species. Cancer in mice can be readily inoculated in other mice. It seems certain too that cancer attacks persons living in the same circumstances and in certain houses. I think I can claim to be the first to publish the particulars of three persons unrelated having cancer at the same time, in the same house, in a note to THE LANCET on April 2nd, 1904 (p. 929). A gentleman living in London had rodent ulcer of the face on which I operated several times. His wife had cancer of the breast from which she died some two years after operation and the gentleman's partner who lived in the same house died from cancer of the tongue. I think there is much more evidence of contagion among persons of advanced age and weakened resistance subjected to local irritation than there is evidence of hereditary transmission.

When we pass in review defects of the nervous system we are compelled to admit that a hereditary disposition in these cases is often very strongly marked. In the case of idiots Shuttleworth and Fletcher Beach found in 21·38 per cent. hereditary mental weakness (insanity or imbecility) and in 20 per cent. epilepsy and allied neuroses, and parental intemperance in 16·38 per cent. Whether disuse of the brain in the parents may be regarded as predisposing to idiocy some probably would be inclined to question but the late Langdon Down gives some interesting statistics concerning the children of the three learned professions, law, medicine, and the church. 3 per cent. were the children of lawyers, 4 per cent. the children of medical men, and as many as 18 per cent. the children of clergymen in his asylum for the children of the better classes. He explains this by supposing that for success in law there is required the greatest amount of mental and physical vigour, that in medicine the race is less urgent and the claims not so imperious, whilst in the clerical profession a moderate success is still more insured and there is less claim among the rank and file for great mental and physical exertion. Galton approached this question from the opposite standpoint. He took the members of the councils of the most prominent scientific societies of London and found that the legal profession furnished 11 per cent. of the foremost men of eminence. The medical profession gave origin to 9 per cent. of scientific men, whilst the clergy gave birth to only 6 per cent. of men of science. The gradation, being similar though not the same, renders these two observers' facts taken together extremely suggestive. To turn for a moment to a more inviting subject, that of genius, I think it is generally admitted that Galton in his book on "Hereditary Genius" proved that where a genius had once been developed exceptional ability was apt to be shown by many of his immediate descendants and in some instances for several generations. Havelock Ellis has attempted to show that there is a relation between genius and stature. Taking the average height of these islands as given by the Anthropometric Committee of the British Association as from 5 feet 4 inches to 5 feet 9 inches he proceeded to make a table of all the recognised geniuses and found that [illegible]e above 5 feet 9 inches, or tall, and 125 below [illegible] inches, or short, and only 74 were between these [illegible] so that he concluded that genius abhors the middle [illegible]

There are some nervous affections which are very hereditary and are prone to attack individuals of a certain stock at a definite period in their lives as if certain parts of the nervous system owing to some original defect were liable to wear out before the rest. Mr. D. S. Gerrish at the Clifton meeting of this society held in June last related the history of a family in which he had traced through five generations a special paresis always affecting the distribution of the anterior tibial and peroneal nerves, commencing between the ages of 22 and 26, and leading to muscular atrophy. It attacked females as well as males and he had traced it in 16 individuals belonging to this family.

Galton and Karl Pearson have attempted to show that hereditary peculiarities are transmitted in definite proportions so as to be capable of being expressed with mathematical precision. Galton took stature as his standard to work upon, premising that what would be true of one quality, physical or mental, would be true of all. He came to the conclusion that hereditary peculiarities were transmitted in the proportion of one-third to a son, two-thirds to a daughter, two-ninths to a nephew, and one-tenth to a grandson. Pearson working at the resemblance of brothers found that the measure of these, indicated by the well-known regression line, was as 2 to 1—that is to say, that if one of the pair exceeded the mean by a certain amount the other of the pair tended to exceed the mean by half the amount; and similarly in respect of defect from the mean. This was always true for all the physical characters yet worked out in man. He then extended his observations to ability and intelligence and found as the result of many observations made on 1918 pairs of brothers that the index worked out almost precisely the same—i.e., as 2 to 1. He concluded that the psychical characters were inherited precisely as the physical and that though education might aid, it could never create, intelligence—"it must be bred."

Deaf-mutism is a condition which has been supposed to be attributable largely to in-breeding, but the evidence as to this does not appear to be absolutely conclusive.[4] Certain it is that if a deaf-mute has appeared in a family the defect will almost certainly appear in other members of the family, among cousins or indirect descendants. Deaf-mutism probably depends on various defects both structural and nervous which may vary in transmissibility. Edward Cock found absence of semicircular canals, or cochlea, and closure of the *fenestra rotunda*, reversions to a simple type, whereas others have attributed the defect entirely to nervous lesions. It is often associated with idiocy in Switzerland where in some cantons 1 in 206 is a deaf-mute.

One of the most remarkable of hereditary diseases is hæmophilia which selects only the males on whom to produce its effects, yet it is only transmitted by the females of a family. Nothing apparently seems to be known of the pathology of this peculiar disease, but the mode of transmission is not peculiar to bleeders; for colour-blindness almost invariably follows the same law. Earle traced colour-blindness through five generations, and out of eight families there was only one in which the defect was not strictly limited to the male sex, but it was always transmitted by the females; nine-sixteenths of the males were affected but only one-fifteenth of the females.

---

[4] In-breeding, according to Shuttleworth and Langdon Down, simply causes a concentration of any particular tendency.

Polydipsia has been stated by Gee to follow the same law, attacking the males and being transmitted by the females. Of the various congenital defects of the eyes which have been shown to be hereditary, total absence of the iris, coloboma, and irregular pigmentation of the membrane have been noted in successive generations. Amaurosis and congenital cataract, external and internal strabismus, dependent on errors of refraction, are all liable to be transmitted. Nyctalopia, or day-blindness, and hemeralopia, or night-blindness, are both hereditary. Albinoes all more or less suffer from nyctalopia, and hemeralopia has been traced by Cunier through six generations.

If we now proceed to consider external defects and deformities we shall find abundant evidence of hereditary transmission through many generations. Of skin diseases ichthyosis is one of the most remarkable and in the family of the celebrated porcupine man Lambert, who was exhibited at the Royal Society in 1731, the disease affected the males for four generations and two of his descendants were exhibited in 1802. Psoriasis also shows a tendency to become hereditary and Hutchinson has suggested that it may in this way become the parent of ichthyosis. The same peculiarity in transmission, as noted in hæmophilia and colour-blindness, has also in several cases been noted in regard to ichthyosis—namely, that it may attack only the males and be transmitted by the females.

The most remarkable instances of hereditary transmission through many generations are furnished by such deformities as supernumerary fingers and toes and suppression or webbing of digits. In the Guy's Hospital Reports for 1881 I traced through five generations the development of supernumerary fingers and toes. A great-great-grandmother had 80 descendants, of whom 24 individuals, or 30 per cent., were thus affected. Two other deformities were also found in this family—viz., webbing of certain fingers and toes and hare-lip and cleft palate. It would seem that in some cases these supernumerary digits have been reproduced after amputation and even re-developed after a second amputation. I have never met with this experience in my own practice, but Darwin quoted three instances in which it occurred and explained the recurrence as due to "reversion to an enormously remote, lowly organised, and multidigitate progenitor." It is known that the fins of fishes may be reproduced after amputation and the salamander's feet and tail will grow again after removal even to six times. Not less tenacious of reproduction in successive generations is the suppression of certain phalanges resulting in shortening of the fingers or their complete absence. A case is quoted by Sedgewick in which this was traced through the female line for ten generations. Ogle described in 1872 a case in which the first and second fingers and the second and third toes had only two phalanges, whilst the third and fourth fingers and the fourth and fifth toes had each only one phalanx. He traced this defect through three generations and through collaterals living in distant places, at Manchester and Lincoln. Tubby has published particulars of a family in which the feet were like lobster claws, the three central toes being suppressed, whilst the hands had each only one finger, the fifth. He traced this deformity through four generations and, in spite of the admixture of new blood, 15 out of 22 descendants were deformed. Many other defects and deformities which are hereditary I have only time to mention. Congenital dislocation of the hip has been transmitted through four generations. Absence of the patella has been noted in three successive generations. Webbing of the toes and fingers has been traced through three and four generations. Club-foot is often hereditary; so are hare-lip and cleft palate. In respect of this deformity it is interesting to note how a slight defect in one generation may foreshadow a more serious abnormality in a succeeding generation.

In the Transactions of the Clinical Society for 1888 will be found a paper in which I showed that a congenital absence of the lateral incisor tooth was an indication that a hare-lip or cleft palate in the same plane might follow in a successive generation. I now for the first time make public a further observation in relation to this deformity. It is that a feebly developed lateral incisor on one side in the mother may foreshadow a hare-lip and cleft palate in her offspring. I have twice noted this association and I exhibit to the society a photograph and drawing of the teeth of a mother, showing this defective lateral incisor, whose first and only child has hare-lip. Hare-lip and cleft palate are frequently associated with other deformities which apparently present no causative relation. I mentioned that in the family with supernumerary fingers and toes which I recorded hare-lip and cleft palate had also appeared in the later generations. Roux has recorded a similar association. Cooper Forster recorded particulars of a family in which imperforate anus was associated in several instances with hare-lip and cleft palate.

Our Transactions already contain several instances of multiple congenital deformities. In the first volume Carpenter relates the histories of two sisters who presented many abnormalities and were of weak mental capacity. Each had a keel-shaped skull, congenital heart disease, abdominal ruptures, webbed fingers, and six toes on each foot. Jackson Clarke describes a case of absence of the radius causing club-hand associated with macrostoma. In the second volume Hutchison and Sutherland each relate a case of multiple deformities of almost identical characters. Two boys, one aged 13 months and the other two years, presented the following abnormalities in common: (1) congenital heart disease; (2) rudimentary hare-lip; (3) six digits on each hand; (4) shortening of all the long bones of the extremities; and (5) defective development of the gums. The shortening of the limbs and the spreading of the fingers and toes resembled cases described as achondroplasia, but other defects were superadded and Shuttleworth thought that their intellects were defective. In the third volume Lewis Marshall gives particulars of a family at Nottingham in which truncated fingers and toes had occurred for five generations and in some of those affected double or supernumerary thumbs had been noticed. This family defect so closely resembles that described by Ogle in 1872 that one is almost inclined to think that some of the same family which Ogle found in London, Manchester, and Lincoln had found their way to Nottingham. I have not time more than to mention the tendency of partial hypospadias to be reproduced or exaggerated in succeeding generations. Hernia, varicocele, and varicose veins are often found hereditary, so is atrophy of one testis.

I wish now to make a few remarks on constrictions and so-called intra-uterine amputations, as they probably are closely related in cause and effect. The remarkable case shown at the Clifton meeting of this society by Mr. H. E. Harris, in which there were complete absence of both lower limbs and of the left upper extremity and webbed fingers on the hand of the only limb remaining, will sufficiently illustrate intra-uterine amputations; and the no less remarkable case of deep encircling constriction of the abdomen associated with a depressed furrow above the left knee published by Dr. C. O. Hawthorne in the third volume of our reports and in THE LANCET,[5] and another shown by Mr. H. J. Curtis of multiple dimpling and grooving of the surface associated with club-feet will illustrate the simpler condition. The most generally received explanation of those constrictions and amputations is that they are caused by the umbilical cord. I am inclined to think that there is little more to be said in favour of the constricting funis theory of intra-uterine amputation than there is for maternal impressions which I will not waste the time of the society by arguing against. If the funis were so tightly wound round a limb as to cause amputation surely the counter pressure on the cord itself would stop the whole fœtal circulation and kill the fœtus. Again, if the funis ever causes amputation, considering the extreme frequency with which it is found round the neck of the newly born child amputation of the head would be one of the most common of the intra-uterine amputations. Then taking Harris's case, is it likely that a cord could first amputate both lower extremities at the hip-joint and then proceed to amputate one upper extremity at the shoulder-joint? The number and the level of these three amputations completely dispose of the theory. If the funis amputated one it would thereby be so relaxed as to lose its constricting influence on the others. Even supposing it possible, the webbed fingers on the only limb still remain to be explained. Then what of the amputated fingers and toes? Will the funis in any way account for the loss of eight fingers and eight toes? Or, could it pick out the three central toes and take off the thumb and three first fingers of each hand as in Tubby's [illegible] cicatrix at [illegible] be caused by [illegible] that the constriction is below the level of the umbilicus and does not run up to it as one would expect if caused by the funis. The grooving of the thigh and the double grooving over the loins to me suggest the probability of a general condition rather than the mechanical effect of the cord. Curtis's case is accounted for on the additional theory of amniotic adhesions of which there is no evidence. The multiple dimplings and grooves are probably to be accounted for by errors in development similar to those which caused the clubbed feet, present in that case.

---

[5] THE LANCET, August 8th, 1903, p 374.

I[illegible] ca[illegible] [illegible]mence in a family and then cling tenaciously to subsequent offspring in spite of fresh blood being added at every generation? They seem to suggest a defect very far back in the procreative process and the frequency of many associated defects implies something very general. An incompatibility of germ and sperm cell, such as produces hybrid deformities in plants, appears to me a not unreasonable hypothesis as the cause of defects dating back to the earliest stage in development

Next to this, considering the vast number of deformities which are associated with defects in the nervous system, as in many of the cases I have mentioned in illustration, a defective nerve control will be a sufficient explanation of many defects occurring at a later period. Morphœa or scleroderma is often symmetrical and by many is thought to be governed by nervous distribution. Such a condition, to my mind, offers a better explanation of intra-uterine amputations than any mechanical one of the cord. There is yet another way in which suppression of an extremity might be accounted for—that is, by supposing a cutting off of the blood-supply through an endarteritis similar to the endocarditis which often [illegible] cause of congenital h[illegible] e artery by embolus, bu[illegible] n [illegible] or the associated deformities such as webbed fingers and the like.

The most difficult of all deformities to account for are those in which there is an excess of the normal development, as with supernumerary digits, if Darwin's reversion theory be not accepted, but the frequent association of these with lack of completion in other parts indicates a general failure of control in the developmental process. Many defects, such as hypospadias, imperforate anus, and cleft palate and hare-lip, are due to a failure to complete the normal process, which a lack of nourishment may to some extent account for. This was almost proved to be the cause of the lion cubs in the Zoological Gardens being born with cleft palates, for with a more liberal and appropriate diet cubs were born normal. But what it is very important to bear in mind is that a defect in development once established is very difficult to eradicate from succeeding generatio[illegible] then com[illegible] [illegible]*anny of the ancestor* from his [illegible] ery desire to escape [illegible] Happily the other side of th[illegible] that a vigorous and manly constitution with high intellectual qualities may be transmitted if the parents do not transgress the laws of mental, moral, and physical hygiene. Physical deterioration, with which mental degeneration almost certainly becomes associated, rests on two factors; the defective health of the parents and the unhealthy surroundings and deficient food of the offspring. Of these two factors the parents exert the greater influence, because in them is summed up not only the result of their own unhealthy lives but that of their ancestors. Much, no doubt, can be done for the child by good food, good air, and mental and moral training, but he must carry the *tyranny of his type* to the end of his days. The Shetland pony, stunted by centuries of bad feeding, cannot in a generation be converted into either a race horse for speed or into a shire horse for draught. The regeneration will be gradual however desirous we may be to hasten it. But to the two ends indicated—to inculcate the laws of health among parents and to secure good food, air, and mental and physical training for the child—to these ends philanthropy may well be directed.

The Croonian Lectures

ON

BRIGHT'S DISEASE AND ITS VARIETIES

Delivered before the Royal College of Physicians of London on June 7th, 9th, 14th, and 16th, 1904,

BY JOHN ROSE BRADFORD, M.D., D.Sc. LOND., F.R.S.,

FELLOW OF THE COLLEGE; PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE, UNIVERSITY COLLEGE, PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

LECTURE III.[1]

Delivered on June 14th.

NEPHRITIS AND ACUTE BRIGHT'S DISEASE.

MR. PRESIDENT AND GENTLEMEN,—It will be seen from the consideration of the facts brought forward in the second lecture that the tendency of recent experimental work is to enlarge considerably the range of action of renal poisons and to suggest that nephritis and Bright's disease are probably in the great bulk of instances of toxic origin, although it must be admitted that at the present time there is no very definite evidence in all instances as to the nature of the toxic agent.

We are, perhaps, justified in considering that the toxic substance producing renal disease in the human subject may be divided more or less arbitrarily into three groups. The first, and on the whole perhaps the most important, consists of the toxic substances which are presumably formed in the course of febrile illnesses and more especially in acute specific diseases. Secondly, the toxic substances ingested, of which the most notable instances are, on the one hand, alcohol and, on the other hand, lead. Thirdly, it is possible that substances having a deleterious action on the kidney may be produced as a result of altered metabolism. The poison of gout is, of course, the most marked instance of this although it is difficult to be certain as to this since it is quite possible that the renal changes in this disease may really be dependent on the action of some poison that is ingested.

The relation of nephritis to acute infective diseases is so well known that only some of the points of interest need be touched upon. It would seem that the severity of the renal lesion is not in any way necessarily related to the severity of the specific infection and this is especially seen in the case of scarlet fever, where the most severe nephritis may occasionally follow an attack of scarlet fever so slight as to have been scarcely recognisable. This fact, which is well recognised as regards scarlatinal nephritis, is also to be seen in the case of other forms of infective disease and it is especially important to recognise it in the case of syphilis. Nephritis owing its origin to syphilitic infection is probably more common than is usually supposed and certainly some of the most severe forms of the disease may occur in cases where the syphilitic manifestations have not been unduly severe. Personally I think it is probable that some forms of so-called idiopathic Bright's disease or nephritis frequently attributed to the action of cold are really dependent on the action of syphilis. It is not uncommon to see well-marked Bright's disease in the first two years after syphilitic infection where the real etiology of the disease may perhaps be discovered quite accidentally, [illegible] a syphilitic rash slight [illegible] presents in some respects [illegible]ered more in detail later.

The only point I wish to insist upon at present is that the virus of this disease, just like that of other acute specific diseases, is capable of producing a profound nephritis characterised amongst other things by a very profuse albuminuria and in my opinion this malady accounts for some of the cases of Bright's disease seen in young adults and attributed to cold owing to the absence of a history of the occurrence of the more usual acute specific infections giving rise to nephritis. Although the action of toxic agents whether ingested or produced through the agency of acute specific infections is probably the most important cause of nephritis and Bright's disease there are in addition various other subsidiary causes which may be of interest and of importance. Thus age and sex play a part, the disease being one more prevalent in the young and in the male. But here it is difficult to appreciate accurately how much is dependent on real sexual differences and how much on sex affording a greater opportunity for the action of these poisons, as, for instance, in the cases of lead, syphilis, and alcohol. As regards age, however, there can be little doubt that the form assumed by the renal disease is to a considerable extent influenced by age and it may be said, speaking broadly, that some of the most severe forms of true Bright's disease are essential diseases seen in the young. Another subsidiary cause or influence that is occasionally seen is the occurrence of the disease in several members of the same family and the disease has even been observed affecting several members of the same family in childhood. Instances have been quoted where several children have suffered with granular kidney and it has been suggested that in some of these the malady may really be due to a specific taint. One of the most interesting conditions associated with Bright's disease is the fact that this malady not uncommonly affects kidneys which are congenitally malformed. Several instances of this have fallen under my observation. This, although of no clinical importance, is of some pathological interest.

---

[1] Lectures I. and II. were published in THE LANCET of July 16th (p. 125) and 23rd (p. 191), 1904, respectively.

One of the principal problems in connexion with this subject is the differentiation of the different forms of nephritis and of Bright's disease. Many writers look upon nephritis and Bright's disease as more or less synonymous terms and not a few advocate the giving up of the term Bright's disease and suggest that all forms of so-called inflammatory renal disease should be classified under the term of nephritis, the various forms of the affection receiving other clinical names, such as acute or chronic, or else pathological designations, such as tubular or interstitial. The term Bright's disease was applied, of course, in recognition of Bright's great discovery that certain forms of albuminuria associated with dropsy were accompanied by gross structural lesions in the kidney and if his name be applied to all the conditions in which albuminuria, dropsy, and gross structural lesions are found the number of diseases which must be included under the term of Bright's disease is necessarily very considerable. It would include, not only various forms of what are spoken of by many pathologists as acute and chronic nephritis, but it would also include such conditions as waxy degeneration, the true granular kidney, and might even be stretched to include such conditions as the cystic kidney or the congenital cystic kidney. It is obviously inconvenient to include such widely different pathological processes as those producing the so-called large white kidney and those producing a red granular kidney and the amyloid or cystic kidney all under one term of Bright's disease. This is inconvenient, not only owing to the difference in the etiology of the conditions, but really much more so owing to the profound difference in the clinical course of the different maladies and it renders all progress in attempting to associate given symptoms with certain lesions very difficult. On the other hand, to give up the term of Bright's disease and simply to speak of its various forms as some one or other variety of nephritis, acute, chronic, tubular, interstitial, &c., is similarly inconvenient owing to the profound differences which exist between the different forms of acute nephritis.

It matters little what names we apply to these conditions provided we recognise that there are a great number of different lesions with a more or less distinct group of symptoms and a distinct natural history, but to group all these different inflammatory affections of the kidney under the term nephritis is to produce as much confusion as that existing at the present time owing to the tendency of many writers to talk of all kidneys as granular kidneys the surface of which presents a granular appearance. No doubt in one sense these kidneys are granular, but to include in one group the roughly granular kidney seen in the young adult where the kidney is small, mottled, or even white, the urine abundant and loaded with albumin, with that seen in a middle-aged or elderly man where the kidney is red, finely granular, often associated with profound arterial lesions and where the albuminuria is slight or even absent produces only confusion. It is doubtless difficult and perhaps impossible to draw a hard-and-fast line between nephritis and Bright's disease, although it is not difficult to separate the more extreme varieties of these affections. At first sight it might seem that the severity of the effects produced by the lesion might be used as a criterion of distinction, using the term nephritis for the more trivial acute affections and the term acute Bright's disease for the more severe. This, however, is unsound from a pathological point of view and also from a clinical standpoint, inasmuch as cases of extreme severity and even causing death may be included under the description of nephritis rather than of Bright's disease, as some of the more conspicuous symptoms of the latter illness may be absent.

The term Bright's disease, as stated above, was originally employed to characterise a condition in which urinary and renal changes were associated with the presence of dropsy and it would seem on the whole, although not an irreproachable classification, that the most satisfactory way out of the difficulty would be to restrict the term nephritis to certain conditions running an acute course in which although renal lesions and urinary changes are present yet dropsy is absent. Doubtless a very considerable number of different renal lesions of varying degrees of severity would be included under this one common heading, but this is more or less inevitable whatever system of classification is adopted. The term acute Bright's disease might on the other hand be applied to the condition where along with renal and urinary changes dropsy is present. As long as one's attention is restricted to the consideration of acute renal lesions this classification is on the whole satisfactory, as every physician must recognise that there are, broadly speaking, two groups of cases of acute inflammatory affections of the kidney, one where all the physical signs and symptoms are, so to say, urinary and the disease reveals itself merely by an alteration in the nature of the urine, and the other where along with the urinary changes dropsy is present.

It has been argued, and may doubtless still be argued, that the separation into these two groups is more or less artificial, inasmuch as the etiology is very often if not identical at any rate similar; and many writers, if not most, dealing with the subject, although recognising the two conditions, have looked upon the one as merely a more serious or extensive or advanced form of the other. In other words, they have recognised that nephritis may be, so to say, of slight severity and unaccompanied with such a phenomenon as dropsy, or, on the other hand, that it may be severe and dropsy a marked feature. Some authors have been so influenced by this consideration as to be inclined to drop the term acute Bright's disease and to speak of all those acute renal affections as acute nephritis, retaining the word Bright's disease as a distinctive term for certain forms of so-called chronic nephritis. It is probably, as I have already mentioned, of but little importance what names we give to these conditions provided that we recognise the existence of these two definite forms of disease.

Many writers, as I have just stated, look upon the form of nephritis accompanied by dropsy as merely a more serious variety of acute nephritis. This, however, is a view which cannot be accepted either on experimental or on clinical grounds. It is doubtless true that where dropsy occurs as an accompaniment of acute renal inflammation the quantity of urine is greatly diminished, but neither experimental pathology nor clinical medicine affords any support to the view that the occurrence of the dropsy is dependent merely on the diminution in the renal secretion. The renal function may be suppressed experimentally, as we have seen, by removal of the kidneys, by ligature of the renal arteries, by ligature of the ureters, or by injection of toxic agents causing destruction of the renal tissues. In none of these conditions, although the flow of urine is necessarily completely arrested, does dropsy occur. These results are cogent enough, but still more conclusive evidence pointing in the same direction may be obtained by the study of the results of disease clinically. There are a number of conditions in which life may be maintained for a week or ten days, notwithstanding the complete suppression of urine. In none of these is dropsy a marked phenomenon; in most of them it does not occur at all, and where it does occur it is quite different from the dropsy with which we are familiar at the onset of acute Bright's disease. In acute Bright's disease dropsy may be the first sign and it is always an early one. In complete suppression of urine dependent on calculous obstruction life may be maintained for some ten days and dropsy may be completely absent or at the most in a few rare instances slight pitting has been observed towards the end. This affords a great contrast to the rapid anasarca that develops at the onset of acute Bright's disease and may almost in a few hours, or at any rate in a few days, render a patient unrecognisable In a number of other conditions—as, for instance, thrombosis of the renal arteries or complete suppression of urine from reflex causes—dropsy is similarly absent notwithstanding that life may be prolonged for a *period similar to that seen in calculous obstruction*

The consideration of the urinary changes produced in these diseases will, at any rate, show that the occurrence of dropsy cannot be correlated to the mere suppression of the urinary function. But much stronger evidence than this is obtained from the study of other renal diseases Thus, in the latter stages of congenital cystic kidney it is no uncommon thing for the flow of urine to be diminished very greatly, although perhaps complete suppression is not usual. Yet even in this malady dropsy at all resembling that seen in acute Bright's disease may be said to be unknown, although it is true that in a few isolated instances slight pitting of the skin has been observed

The most conclusive reason, in my opinion, for separating cases of acute Bright's disease from cases of acute nephritis rests in the fact that the occurrence of dropsy even in this disease cannot be [illegible] the inflammatory chang[illegible] true that most cases of [illegible] e of, or as a sequel to, a [illegible] dropsy is absent are slight as shown by the alterations in the composition of the urine yet it is absolutely certain that the most intense nephritis may exist without the occurrence of dropsy Thus the urine may be greatly diminished in amount, loaded with albumin, and loaded with blood, presenting therefore all the pictures of an intense acute nephritis, as severe as any seen in acute Bright's disease, and yet dropsy may be absent We may even go further than this, inasmuch as cases of acute inflammation of the kidney may be seen where after a short period during which the urine is loaded with blood and albumin the secretion becomes more and more scanty and finally suppressed and the patient dies with uræmic manifestations and yet dropsy may be absent We see from the consideration of these facts that neither from the experimental nor from the clinical side is there any substantial evidence that the occurrence of dropsy is to be looked upon as dependent on a mere suppression of the urinary excretion Further, what is more important from our present point of view, acute inflammatory affections of the kidney of the highest degree of severity may exist without the occurrence of dropsy, although even in the fatal cases the duration of life is such that it cannot be asserted that the patients have died too soon for the dropsy to manifest itself One of the specimens of acute nephritis on the table is that of a patient who lived ten days after the onset of symptoms and where complete suppression may be said to have been present, as less than ten ounces of urine were passed during the whole of this period, yet dropsy was absent notwithstanding the intense character of the nephritis I think the conclusion is justified that the occurrence of dropsy cannot be correlated either with the mere suppression of the urinary excretion or with the virulence of the inflammatory changes in the kidney

When we turn to the consideration of the cases of acute *Bright's disease—that is to say the cases of acute inflammatory* renal changes associated with the presence of dropsy—we meet with facts which bear out the same conclusion, as it is quite common to see cases of acute Bright's disease where the dropsy and the general effects produced by the malady may reach a high degree of severity and yet the urinary changes, although well marked and acute, are not necessarily as severe, as measured by the amount of blood and the amount of albumin or even the diminution in the amount of urine, as those seen in the more severe forms of nephritis unaccompanied by dropsy

We have hitherto been considering clinical facts and probably the only difference of opinion amongst different observers would be as to the names to be applied to these two conditions When, however, we attempt to explain the differences between these two great groups of cases we are dealing mainly, at any rate, with theory, but that there are two great groups of acute inflammatory affections of the kidney, one associated with dropsy and one without, must be, I think, regarded as proved We cannot for the reasons advanced above look upon the one as merely a more serious form or development of the other. What is the explanation of the occurrence of [illegible] its absence in the other? [illegible] lue to the mere suppressi[illegible] low and it might be quite [illegible] in the urinary flow as rather the result of the dropsy than its cause, since undoubtedly under certain conditions very acute nephritis may exist without any diminution in the urinary flow Thus acute nephritis may occur as a complication of diabetes and the urine be loaded with albumin and blood and the kidney present the changes characteristic of acute nephritis, and yet the flow of urine may be maintained at the high level characteristic of diabetes This is certainly remarkable as showing that an intensely inflamed kidney may yet be able to excrete very large quantities of urine and makes one hesitate as regards always attributing the diminution in the flow of urine seen in acute Bright's disease to the changes in the kidney On the other hand it is, of course, undoubted, as acute nephritis shows, that usually acute inflammation of the kidney does cause a diminution in the flow of urine A tempting hypothesis is, of course, the well known one that in Bright's disease we have to deal with a toxic substance circulating in the blood and that this produces not only changes in the kidney but also changes in the vessels at large allowing of th[illegible] it would seem at the present [illegible] although by no means proved, [illegible] s we have to deal with a renal poison pure and simple, but in that form of acute nephritis associated with dropsy to which the term acute Bright's disease is applicable a different poison is present affecting not only the kidney but the vessels generally There is unfortunately no direct evidence in support of such a view as this, although there are a number of substances the injection of which may be followed by the production of dropsy These so called lymphagogues show, at any rate, that dropsy may be produced as a result of the presence of abnormal substances in the blood Still, no such substance has as yet been obtained from the blood, the tissues, or the urine in Bright's disease Although the mere arrest or diminution in the urinary excretion is not of itself capable of producing dropsy, yet it is probable that the hydræmic condition brought about as a result of partial or complete suppression of urinary secretion may play a part in the production of dropsy and there is a certain amount of experimental evidence in support of this

Ligature of the ureters in animals, as has been stated already more than once, is not followed by the production of any dropsy Further the injection of considerable quantities of normal saline solution into the general blood stream, although producing a condition of hydræmia, is also not followed by the production of any dropsy If, however, these two procedures are carried out in the same animal ascites is liable to be produced The most marked ascites is produced if after ligature of the ureters through a small incision in the abdominal wall a *moderate venesection is made and this is* followed by the transfusion of normal saline solution A condition of hydræmic plethora may be produced in this way and it would seem that either the peritoneal vessels are normally more permeable than those of other parts of the body or possibly that the condition of the peritoneal vessels has been modified in some obscure way as a result of the operative procedures necessary in order to ligature the *ureters It has not* been possible, however, in the laboratory to reproduce anything comparable to general renal dropsy such as is seen clinically in cases of acute Bright's disease

Notwithstanding the separation of these cases of inflammation of the kidney accompanied by general dropsy from those where the inflammatory lesion produces only effects in the composition of the urine, the number of cases included in the latter group is still very large, and such cases present all degrees of severity from a mere passing or transitory albuminuria to those where complete suppression of urine is followed by death from uræmia It is difficult, if not impossible, to classify these various forms of nephritis in a satisfactory manner, but at any rate one group is more or less sharply separated from the others This is the group where the nephritis occurs during the course of acute febrile diseases and corresponds to what used to be spoken of as febrile albuminuria, but perhaps the name given by French authors to this condition—viz, of transitory nephritis—is more satisfactory The main points of interest attached to this condition are, first, that it is not in any way one immediately serious although it frequently occurs as a complication in the very same acute specific diseases—such as scarlet fever, pneumonia, &c.—which may give rise to the more serious forms of acute nephritis or even to acute Bright's disease. Secondly, the condition is a purely temporary one seen during the height of the febrile disorder and subsiding with it and presumably dependent on the action on the kidney of the toxic agents or toxins elaborated by the morbid process causing the original disease. Further, in many instances the lesions produced in the kidney are not uniform in their distribution but, on the contrary, are disseminated and patchy and therefore partial in their distribution. The degree of development of this transitory nephritis varies enormously in different acute febrile diseases and even in the same disease in different circumstances and unquestionably it is a condition of little or no clinical importance at the moment and, as just stated, it commonly subsides with the subsidence of the febrile disorder. One of the great difficulties as regards the pathology of the serious chronic forms of Bright's disease lies in the fact as to whether this transitory nephritis may or may not lay the foundation of a subsequent progressive lesion of the kidneys. Such an origin certainly cannot be excluded, as it is no uncommon thing to see patients with the most advanced chronic Bright's disease which has run a latent course for many years and the etiology of which is most obscure, and it is, of course, possible that some of these cases may really owe their origin to an attack of nephritis accompanying an acute specific which has produced renal changes and has either been entirely overlooked or else forgotten by the patient.

Another point of interest with reference to these cases of slight nephritis occurring as the accompaniment of acute febrile diseases is the question whether some of the cases of trivial or even of so-called functional albuminuria may not really be due to a slight lesion produced in the kidney by some such inflammatory affection, although other factors must also be at work and the most important of these is probably a functional disturbance of the vaso-motor system. In transitory nephritis or febrile albuminuria the lesion in the kidney is not only slight but, as already mentioned, may be partial in its distribution. It is, at any rate, conceivable that in such cases the glomeruli or the tubules may in some portions of the kidney be sufficiently damaged to allow of the passage of albumin permanently and I cannot help thinking that in some of the cases of slight albuminuria where there is no reason to suppose the presence of a granular kidney some such mechanism as this is at work. In other words, the albuminuria although persistent may not be the sign of a chronic and progressive disease but the relic, so to say, of a former attack of acute nephritis of slight severity, partial in its distribution and of no great clinical importance. We are rather prone to look upon persistent albuminuria as a sign of chronic progressive disease and yet large numbers of patients may suffer from albuminuria for long periods without any very noticeable impairment of their general health. It is possible that in these cases the albuminuria is to be attributed rather to a partial and non-progressive lesion. A similar lesion may, perhaps, also be the cause of some of the so-called functional albuminuria. Although transitory nephritis is more or less sharply marked off from the other varieties the latter are very difficult to classify, inasmuch as all grades of severity are seen. They may, of course, be divided up into glomerular, tubular, and interstitial according to the predominance of the lesion in one or another of these structures, or, on the other hand, they may be classified etiologically according to the agent causing them. Some of the varieties, as for instance that seen perhaps as a result of influenza, are remarkable owing to the amount of hæmaturia which may be present; others, as in scarlet fever, are characterised by the very great diminution in the amount of urine excreted and it is no uncommon phenomenon for complete suppression to occur. In the severe forms associated with more or less complete suppression uræmic phenomena are always prominent and they usually take the form of the more acute manifestations of uræmia, such as vomiting, drowsiness, coma, and convulsions. Epileptiform seizures are probably more frequently seen in the uræmia accompanying severe and fatal acute nephritis than in that seen in the other forms of renal disease with, of course, the exception of eclampsia. The frequency of epileptiform seizures in severe nephritis may perhaps be due to the variety of the disease or nature of the poison, but, on the other hand, it must not be forgotten that many of these cases occur in children and such young patients of course are more liable to epileptiform seizures in a variety of circumstances than adults.

Although the uræmic symptoms seen in acute nephritis are most frequently of the acute or even of the fulminating order, in exceptional instances a clinical picture resembling that of latent uræmia may be seen. A most remarkable instance of this is afforded by the case where acute interstitial nephritis of unknown origin occurred in a girl aged 11 years, causing complete suppression, and where the symptoms presented were practically indistinguishable from those seen in complete calculous anuria. The lesion in this case, although annulling the functions of the kidney, was really an acute interstitial nephritis, the interstitial tissue being gorged with blood and containing innumerable disseminated foci of commencing suppuration. This patient, as already mentioned, lived ten days from the onset of symptoms and during that time passed less than ten ounces of urine. It is possible that the difference in the character of the uræmic symptoms from that most usually seen in acute nephritis is dependent on the lesion being one affecting the interstitial tissue and this case affords further support to the view already advanced that where the excretory functions of the kidney are suddenly arrested, the kidney having been previously healthy, the uræmia produced is of the character known as latent uræmia and that it is only where uræmia supervenes as a result of acute or chronic disease of the renal elements themselves that the more usual acute or chronic uræmia is seen. This is a point of considerable importance to the surgeon especially, inasmuch as there is a tendency to associate the clinical picture of latent uræmia exclusively with obstructive suppression, but it is unquestionable that precisely the same symptoms may be produced where the functions of the kidney are arrested owing to acute disease of the kidney.

It is probable that syphilis plays a considerable part in the production of nephritis and it would also seem that in some instances the nephritis presents peculiar features, thanks to which the probability of it being of specific origin can be surmised. Syphilis differs from other acute specific infections in that it causes a greater variety of lesions in the kidney. Thus it has long been recognised that gummata and waxy degeneration of the organ are liable to occur during the later stages of syphilitic infection. But putting all such cases aside there can be little doubt that a syphilitic nephritis occurs not infrequently in the first two years following specific infection. Patoir[2] showed that the examination of the urine at the onset of secondary symptoms in syphilis revealed the presence of albumin. This albuminuria resembled in many respects that seen in the course of other infective diseases. Very commonly no other symptoms of nephritis were present and the amount of albumin was small. This author considers that in syphilis the urinary secretion tends to become more active and that the quantity and the density of the urine may increase but curiously enough at the moment of the outbreak of the syphilitic manifestations the toxicity of the urine may be diminished and he thinks that in young subjects there is, at any rate, an increased activity of nutrition and that the changes in the urine are mainly dependent on this. In addition to these more or less trivial disturbances in the function of the kidney cases are seen where nephritis of a considerable degree of severity occurred during the incidence or during the convalescence of syphilis. Cases of nephritis are not infrequently seen occurring during the secondary stage of syphilis which are often attributed to the action of cold. It was at one time thought that these more severe cases of nephritis seen during the course of syphilis were really dependent on the large doses of mercury that had been employed in the treatment. But this is not the case, as several instances have been recorded where the nephritis has supervened in patients who have not been systematically treated with mercury.

Delamare[3] considers that where nephritis complicates secondary syphilis the renal lesion is either acute or subacute and there is a certain resemblance between the nephritis of syphilis and that seen complicating scarlet fever. Two cases of syphilitic nephritis have fallen under my observation, one in a young man and the other in a middle-aged woman. In both cases the renal lesion developed during the first year following infection and in both cases it was of a severe form.

Syphilitic nephritis is difficult to distinguish from other forms of nephritis, but there are one or two features as to the clinical course of the disease which may suggest its origin apart from the history of recent infection In the first place, the amount of albumin present in the urine is usually very large, the urine becoming solid on boiling Notwithstanding the very large amount of albumin present the quantity of urine is not so much diminished as in many other forms of nephritis In the instances which have fallen under my own observation blood has been absent Notwithstanding the very large amount of albumin casts are not very abundant and casts consisting of definite renal elements are extraordinarily scanty The patient often does not present any marked phenomena of illness or any marked physical signs other than the presence of a large amount of albumin Thus dropsy may be completely absent Delamare has drawn attention to the fact that one of the characteristic features of the condition is that a milk diet produces very little improvement and no material diminution in the amount of albumin The albuminuria often persists for many months and in one of the cases under my own observation it lasted for over six months but ultimately cleared up absolutely In other cases uræmic symptoms developed and these are necessarily of a more severe type and may be fatal In one case that I have seen death occurred not so much from uræmia as from cardiac dilatation Dropsy is not always absent but where it is present the cases are more or less indistinguishable clinically from other forms of acute or subacute Bright's disease The prognosis of syphilitic nephritis is most uncertain but it would seem that, notwithstanding certain theoretical objections, the treatment of these cases by antisyphilitic remedies is necessary and that mercury should not be withheld owing to any fear of the toxic action of the substance on the kidney In some respects the clinical picture produced by syphilitic nephritis is somewhat similar to that seen in amyloid disease, and of course this affection is not an uncommon accompaniment or sequel of syphilitic infection Still, the differential diagnosis can usually be made owing to the different period in the course of syphilis in which syphilitic nephritis and amyloid degeneration are respectively liable to occur It is important to recognise syphilitic nephritis, as very considerable benefit may often be derived from its early recognition and prompt treatment with antisyphilitic remedies

THE

RED LIGHT TREATMENT OF SMALL-POX

By F F RICKETTS, M D, M R C P LOND,
MEDICAL SUPERINTENDENT OF THE SMALL-POX HOSPITALS OF THE METROPOLITAN ASYLUMS BOARD,
AND
J B BYLES, M.B, B C CANTAB, F R C S. ENG,
ASSISTANT MEDICAL OFFICER AT THE JOYCE GREEN HOSPITAL.

THE treatment of small-pox by red light was recommended to the profession some 12 years ago by Dr Finsen of Copenhagen Since that time it has been tried in several places and has, we believe, come into general use in the Scandinavian countries In this country, however, the treatment has not become established In the course of last year we had an opportunity of testing its value and we were not favourably impressed by it. We think it worth while to publish our results to justify the apparent neglect of a remedy reputed to be of so much value

In a recent article[1] Dr Finsen has expressed his views in very emphatic language and there and elsewhere has laid down very clearly and definitely what his remedy is claimed to accomplish It is not a remedy for small-pox but only for the suppuration which attends it And Dr. Finsen does not claim that its effect is merely to ameliorate the suppurative condition and its consequences, but that it absolutely prevents it He says: "Suppuration will generally not occur and the patients will recover without scars or only with almost invisible cicatrices"[2] "That suppuration is due to light, especially to the blue violet and ultra-violet rays, and may with certainty be avoided if these rays are kept off .. .. rests on a fact established by practical experience."[3] "It may be considered as an irrefutable fact that it is possible to avoid the suppuration and its consequences by protecting the patients from the action of light."[4] "The greatest number of deaths are due to suppuration which, *cæteris paribus*, would be prevented if no suppuration were present Further, the numerous complications and sequelæ due to suppuration may be avoided as well as the disfiguring pitting"[5] "Even in cases of confluent small-pox or in unvaccinated persons the method very rarely fails, supposing, of course, that the patient comes under treatment early enough"[6] There is a suspicious moderation about the last statement Truly, if the remedy fails in confluent small-pox or in unvaccinated persons we shall be better off without it We have not, however, so limited our selection and we think that we are entitled to hold that if in a reasonable number of cases in which the necessary conditions have been fulfilled suppuration and its consequences are shown to be the rule the case for red light, so stated, falls to the ground

Our experience was limited to 13 cases As we were convinced that these patients derived no benefit from the treatment we did not, for reasons which will appear later, consider that we were justified in proceeding further The ward in which they were treated was a small one containing four beds It had six windows, all of which were blocked by a double layer of photographic "ruby" fabric There were two doors, over each of which was hung a curtain made of a double thickness of red "Turkey twill" The doors opened into lobbies and an area round each door was screened off with a double thickness of the same material, so that on passing through the door and under the door curtain one found oneself in a small chamber completely shut in with red curtains One passed again through a second curtain to reach the light The effect of this arrangement was that persons entering or leaving the ward admitted no white light when raising the curtains A few other apertures in the ward through which a dim light penetrated were also screened off with ruby fabric In fact, the ward was converted into a photographic dark room and perhaps we used an excess of caution in our arrangements No candles or naked flames were used at night Artificial light was obtained by the use of dark room lamps with red glass

Fifteen patients were at different times admitted to the ward One of these had an attack of discrete small-pox of the mildest description and was, in fact, taken to the ward by inadvertence Another patient died from heart failure the day following his admission, for which reason his case also may be excluded There remain 13 cases in which the patient was treated in red light throughout the period of suppuration Five were vaccinated, six were unvaccinated, one patient had been vaccinated only in the period of incubation, and in one case the matter was doubtful Four were cases of discrete and nine of confluent small pox The mildest was one of discrete small-pox of a very moderate type of severity and at the other extreme was one of very severe confluent small pox The other cases ranged between these two extremes Two of the patients died, both during the fever of suppuration In neither case was there any complication to which the fatal result could be attributed. Details of the cases are given in the table

Suppuration —What precisely is to be understood by the statement that suppuration is prevented by the red light treatment? For the statement may imply either of two very different trains of events It may mean that the vesicles, even in cases of unmodified small-pox, fail to maturate Or it may mean that as the result of the treatment cases of unmodified small pox do not occur but are resolved into cases of modified small pox where suppuration is at a minimum The fact that suppuration is imperfect is by no means the only peculiarity of modified small-pox If suppuration is imperfect so is vesiculation and so may be the formation of papules The essence of the thing is that an idiosyncrasy of the individual (sometimes natural, more often acquired) so increases the capacity to resist the action of the virus in the skin that processes of repair predominate over processes of destruction In consequence there is a change in the whole course of development of the lesions which differ in their size shape, and rapidity of development and not merely in the fact that suppuration is less in evidence Even in unmodified cases a certain number of lesions may be seen which are small and ill-defined And, on the contrary, in modified cases some large unmodified lesions may often be

TABLE GIVING THE RESULTS OF THE RED LIGHT TREATMENT OF SMALL-POX IN 13 CASES.

No.	Sex.	Age.	Vaccination.	Type of disease.	Result.	Day of efflorescence on which patient entered red ward.	Condition of rash on admittance to red ward.	Duration of treatment by red light.	Highest temperature during secondary fever.	Development of eruption.	Complications and sequelæ.	Remarks.
1	M.	9	Not.	Mild discrete.	Recovered.	First.	Early papular.	8 days.	102° F.	Normal	Albuminuria.	—
2	M.	39	In infancy only.	Severe discrete.	"	Fourth.	Late papular and vesicular.	6 "	100°	"	—	—
3	M.	59	"	"	"	"	Papular and slightly vesicular.	9 "	101·4°	"	Septic ulceration of skin.	—
4	F.	11	Not.	"	"	Second.	Papular; partly vesicular on wrists and ankles.	11 "	101·2°	"	Slight delirium.	—
5	M.	35	At age of 20 only.	Confluent.	"	"	Vesicular.	9 "	Absent.	Modified.	Severe headache in secondary stage.	—
6	M.	39	In infancy only.	"	"	"	Early papular.	12 "	100·2°	Partially modified.	Delirium, septic ulceration, and boils.	—
7	M.	23	Not.	"	"	Third.	Papular with some early vesicles.	9 "	102°	Normal.	—	—
8	F.	4	Two days before efflorescence only.	"	"	Second.	Early papular.	13 "	103°	"	—	—
9	M.	2½	Not.	"	"	Third.	Papular.	15 "	104°	"	—	—
10	M.	3	"	"	Died on the eighth day of efflorescence.	Second.	"	5 "	102·6°	"	Ulcer of cornea, slight laryngitis, otorrhœa.	Died from secondary fever.
11	M.	30	Doubtful.	Severe confluent.	Recovered.	Third.	Papular.	17 "	103°	"	Alopecia, septic ulceration.	—
12	M.	40	In infancy only.	"	"	Second.	Early papular.	19 "	103·6°	"	Albuminuria, delirium, and boils.	—
13	F.	19	Not.	"	Died on the twelfth day of efflorescence.	"	Papular and early vesicular.	9 "	104°	"	Delirium.	Died from secondary fever. Exposed to daylight for about one minute on fifth day of efflorescence.

observed which suppurate as inevitably as they would in a case of unmodified small-pox. In fact, the same kind of lesion runs the same course whatever the nature of the case. Where cases differ is in the kind of lesion which is most plentifully developed.

If, therefore, treatment by red light has the effect of preventing the maturation of unmodified lesions that is an unnatural phenomenon which could hardly fail to be remarked. Certainly we did not remark it. The pustules in our cases were as large and as well developed as usual. In the red light, of course, their yellow colour was not apparent and the lesions had a fallacious appearance of remaining vesicular. We made a practice, however, of drawing off the contents and examining them by daylight and in Case 12, when the patient was taken into daylight to be photographed, we were able to satisfy ourselves that the pustules had developed normally.

If, on the other hand, we are to take it that this treatment has an effect similar to that of vaccination and causes what would otherwise be natural small-pox to assume a modified form then we must look only for an unusual frequency of modified cases. It is obvious that if great care be not taken to eliminate cases modified by vaccination or by a natural immunity it will be very easy to commit the error of mistaking an effect inevitable for one due to the treatment—an error to which many observers seem to have been prone. We realised our own danger in this respect, since the strain of disease existing in London last year was exceptionally benign and cases of all kinds showed an unusual tendency to exhibit modification. We were therefore at some pains to select cases which seemed likely to run an unmodified course. And in 11 cases out of the 13 our selection was justified. Two of our cases (No. 5 and No. 6) did exhibit modification, though one of them (No. 6) did so to only a partial degree. We attributed that result to our own defective judgment. It is, of course, open to anyone to suggest that the result was due rather to the treatment, just as it may be claimed that in the other 11 cases, with another form of treatment, the attacks would have been somewhat more severe. But such a modest claim is not what Dr. Finsen makes, not what we pretend to rebut, and not, we may add, what anyone has yet attempted to establish. Those "sequelæ due to suppuration" which the red light treatment is claimed to prevent, such as boils, ulceration, and the like, were very much in evidence in some of our cases.

Suppurative fever.—The presence or absence or the degree of suppuration are facts which can be described but not illustrated. The amount of suppurative fever can, however, be precisely recorded. The controversy as to whether or not suppuration is abolished or diminished by the red-light treatment appears to us to be beside the mark, since what matters is not the suppuration but its consequences—fever, scarring, and death. The fever of suppuration begins between the fourth and sixth day of efflorescence and any pyrexia occurring before that time may be ignored for our purpose. It will be seen that all the cases, with one exception, exhibited some rise of temperature. Secondary fever was absent in a case of modified confluent small-pox (Case 5). But suppression of the secondary fever is not an unusual occurrence in such cases. The fever was slight in some of the milder cases. In the more severe it was higher and in some it was considerable. It will be observed that in the mildest case, that, too, in which the treatment was begun earliest, the suppurative fever was rather pronounced. We are far from believing that the treatment had any effect in diminishing the suppurative fever in any of our cases.

Scarring —A good deal has been said about the effect of the treatment in preventing pitting from small-pox It may be worth while stating that with any rational treatment of small-pox scarring is absent in the majority of cases Pigmentation is commoner but it is not lasting It is chiefly *in severe and unmodified cases that scarring is pronounced* We certai [illegible] xceptionally favoured i [illegible] ered without scars and [illegible]

The time of inception of the treatment —To physicians in whose hands this treatment has failed it has been objected either that the exclusion of white light was im*perfect or that the treatment was not begun early enough* To the former objection it is certain that we have not laid ourselves open And with regard to the latter we may remark that if objection is to be made on this score then the treatment ceases to be applicable in a small-pox hospital. It does not appear, however, that those who have been more fortunate in their results have applied the treatment earlier Dr Finsen claims that suppuration *is prevented if the treatment* is begun before suppuration is imminent This condition was fulfilled in all our cases In most the eruption was either partly or wholly papular and in some the development of papules was still incomplete. The rate at which efflorescence and vesiculation proceed differs a good deal in different cases and we rejected cases in which vesiculation was advanced even though the patients were in an early stage of the illness counting by time As a rule the first sign of suppuration is to be noticed on the fifth day of efflorescence (about 96 hours after the first appearance of the papules). The majority of our cases came under treatment on the second or third day (24 or 48 hours after the beginning of efflorescence) In two cases only was the treatment delayed for 72 hours (till the [illegible] 1) it began within a [illegible] ie rash.

[illegible] has any of the merits which have been claimed for it Others observers who have tested it, as we have done, in selected cases, appear to have arrived at similar results So far back as 1893 Juhel-Renoy[7] submitted 12 patients to the treatment and found no evidence *in favour of it His unfortunate results were attributed by* Dr Finsen to an imperfect exclusion of light He does not specify on what grounds this criticism was based Indeed, Juhel-Renoy's methods seem to us to have been stricter than those adopted by some observers whose results Dr Finsen has approved. We suspect that it was the results which earned the criticism and the method which received the blame

We attach the more importance to Juhel-Renoy's results because he had a fairly extensive experience of small-pox, having treated 2000 cases Oettinger,[8] with a more limited experience (he had treated 250 cases), tested the treatment in eight selected cases of confluent and semi confluent small-pox. Three of the patients died. The five who recovered were all vaccinated Oettinger was of opinion that the *course of the eruption was modified in these cases and that* would probably be so, in some of them at any rate. But three of the five cases developed a marked secondary fever and most of them were scarred Oettinger, who gave the treatment a modified approval, admitted that in these respects his case [illegible] anish physicians [illegible] respect of scarring, [illegible] so well under a different treatment, no one, particularly no one with Oettinger's limited experience, could possibly determine beforehand how much fever and scarring to expect. It is enough for our purpose to point out that he did not prevent that train of events—fever, scarring, and death—which the treatment is reputed to avoid

We may also refer to two case [illegible] Philadelphia *One patient had* [illegible] suppurative fever and died Th [illegible] badly scarred It is only the [illegible] exaggerated claims that have been made for the treatment which give pertinence to the results obtained in two isolated cases

Our own results and those which we have quoted being so widely at variance with the claims made for the treatment it is a matter of some interest to inquire what justification the advocates of the treatment have for the faith that is in them For the question remains whether, without abolishing suppuration and its consequences, the treatment has any *sort of beneficial effect in this disease Our own and the* other cases do not preclude such a possibility To test this question would involve a more prolonged and a comparative trial in which we are under no obligation to engage unless a *primâ facie* case has been made out by those who advocate the treatment

We may be excused for pointing out that there are two *methods of testing the efficacy of a remedy. Where the* course of the disease is fairly constant (as in lupus), or even when this is not so, where a sufficiently accurate prognosis is possible, it is enough to apply the remedy in a limited number of cases But if the disease is a very variable one it is often necessary to apply the statistical method and to compare large groups of cases with similar groups separated *for purposes of control In proportion to the variability of* the disease on the one hand and to the insignificance of the effect of the remedy on the other the size of the groups must be increased to eliminate accidental errors. The method adopted by most observers who have commended this treatment has been to take a very limited number (as a rule not more than one or two dozen) of unselected cases—cases, that is to say, as they presented themselves, vaccinated and unvaccinated, mild or severe as might happen—and to draw their conclusions from the event They have dealt with ten where hundreds were necessary and as a rule they have not concerned themselves with control cases

Small-pox is a disease where such looseness is particularly unfortunate because, apart from variations owing to individual differences in natural susceptibility, we have to reckon with the *disturbing factors not of vaccination only but of* variability in the strain of disease To illustrate the latter point we may instance the fact that the fatality from small-pox in London in 1902 was over 17 per cent In 1903 it was less than 4 per cent Had we proceeded last year to test the Finsen treatment by treating with red light all our cases, or an unselected minority of them, to what a false *conclusion this disturbing factor would have led us It is* just as unsafe to neglect differences effected by vaccination in the susceptibility of communities This treatment originated in Scandinavia and has its home there We suspect that to be due less to the virtues of the treatment than to the commonsense of those communities which do not disregard the safeguards of vaccination

Of the cases published by Scandinavian observers the largest series was one of 62 by Backman[10] of Viborg For the cases of other observers we have not been able to obtain access to the original papers but the results are quoted in Finsen's "Phototherapy" The largest series were 23 by Abel of Bergen, 22 by Mygind of Naskov, 16 by Benckert of Gothenburg, and 11 by Feilberg of Copenhagen. The total number of deaths in these 134 cases was 11, a *fatality of 8 2 per cent* Dr Finsen mentions 15 other cases treated by various other Scandinavian observers without a death and their inclusion would make the fatality 7 3 per cent We are not aware how these figures compare with the fatality in small pox commonly observed in Scandinavian countries but they would not be very unusual in London The fatality is the only indication that we have to judge of the course pursued in these cases, since there is a remarkable absence of all other essential information about them We do not know how many of the patients were vaccinated or what was the type of disease from which they suffered As a rule, there is no exact information about the extent of the secondary fever Though we have no means of knowing on what basis the claims rest the authors speak of favourable results having been met with *in respect of suppuration, fever, and scarring* Most of them admit, however, the occurrence of one or another of those events in some of their cases Backman, for instance, speaks of suppuration and suppurative fever (from which some of his patients died) The peculiarity of his cases seems to have been that none of them were scarred.[11] It is difficult to avoid the suspicion that the supposed peculiarities in these several results were due chiefly to a limited experience of the disease on the part of the observers. For instance, in Finsen's "Phototherapy" the photographs and temperature charts are published of three cases treated by Feilberg and Benckert. Two were cases of severe discrete and one of modified confluent small-pox. The illustrations we presume to be given to show the favourable effect of the treatment. But not in the character of the eruption, in the extent of secondary fever exhibited, or in the amount of scarring stated to have been developed can we see that these cases were remarkable.

---

[7] Bulletin et Mémoire de la Société Médicale des Hôpitaux de Paris December, 1893

[8] Semaine Médicale 1894

[9] Journal of the American Medical Association, May 2nd, 1903 Dr Schamberg in this paper which we had not seen when the above was written, makes a valuable critical analysis of the theoretical considerations and practical results on which the red light treatment is based

[10] [illegible]

[11] [illegible] scarl [illegible] more [illegible] upon those theoretical principles on which the treatment is based

When these authors speak of the absence of suppuration, fever, and scarring in their cases we shall probably be right in concluding merely that those phenomena were not prominent in the majority of their cases. But even in communities like our own, only partly protected by vaccination, most of the cases escape those incidents. The point is capable of illustration in the case of secondary fever. We have taken at random the first hundred cases completed in our hospital during the current year and we find that 30 were unvaccinated and that there were 12 deaths, indications of a type of disease severe beyond the ordinary. Yet most of the cases presented no secondary fever whatever and (excluding the 12 fatal cases) in only six did the range of temperature exceed 39° C. (102·2° F.). In a better vaccinated community and with a milder strain of disease it would be possible to give a handsome testimonial to any sort of treatment by following the lines of the Danish physicians.

A few series of cases have been published by physicians in other countries. 18 patients were treated by red light by Dr. J. T. C. Nash[12] of Southend. He compares his cases with another series of 12 (which, however, did not synchronise with the first) treated in daylight. Dr. Nash speaks in very guarded terms of his results and we do not think he would ask us to suppose that the difference in fatality between 25 per cent. and 5½ per cent. is attributable to the treatment adopted.

Casassa[13] has recorded the treatment of six patients by red light. All were vaccinated. The results are stated to have been favourable but the paper does not call for serious comment. The treatment has also been approved by Engel[14] who had some experience of it in Cairo. We have not been able to consult his paper.

We know of no other published observations favourable to the red light treatment. But on the other side we have a series of about 300 cases recorded by Brayton[15] of Indianopolis. Brayton has not published details of his cases but he took the precaution of treating at the same time an equal number of patients in wards lighted by the ordinary methods. He found that in no respects did the patients under the red light treatment do any better than the others. Suppuration, fever, scarring, and death were all unchecked.

We think that we have succeeded in showing not only that the case for this method of treatment is not proved but that no serious evidence has been advanced in favour of it. We would recommend those who are disposed to practise it to do as Brayton has done and to treat at the same time an equal number of patients in ordinary wards. We would suggest also that as it only clouds the issue and prolongs the trial to include the mass of mild cases in vaccinated persons it would be better to limit the trial to unvaccinated patients. When a sufficient body of evidence in support of the treatment has been collected on these lines it will be time enough, it seems to us, for the matter to be pressed on the attention of the profession. We are not ourselves disposed to embark on the inquiry for the reason that we derived from the study of our cases the very unpleasant impression that the effect of the treatment was harmful. We thought that it had an unfavourable effect on the general condition of the patient. The tendency to mental symptoms (delirium, headache, restlessness, &c.) seemed more marked. The suppurative fever, too, appeared to us to range higher than might have been expected. It is true that we found the patients did well in respect of affections of the eye. That was to be expected. But, on the other hand, we thought that they had more than their fair share of the other septic sequelæ of small-pox.

We cannot say how far these impressions were justified by the facts. Assuming that we were right it is, of course, possible that some of the results were attributable to the oppressive gloom and colour of the ward. But our objections lie deeper than that. For not only was it difficult to keep a close watch on the development and progress of the eruption and on the patient's condition, but it was difficult to carry out those personal and general hygienic measures on which the successful treatment of small-pox so much depends. Above all, in excluding light we must necessarily limit the supply of air. In all suppurative conditions, and especially in small-pox, not only an abundant air space and good ventilation but the freest circulation of air is essential. Any form of treatment which puts a check on the supply of fresh air must be regarded with suspicion unless it brings solid advantages in compensation. That substantial advantages do not attach to this form of treatment we feel sure. We therefore hope that this paper may have the effect of discouraging further application of the remedy in this country. But we venture to appeal also to Dr. Finsen, who has done so much for suffering humanity, to cease to lend the weight of his authority to support a method of treatment which, if it is inefficacious, must necessarily be inhumane.

SLEEPING SICKNESS: A RÉSUMÉ.[1]

BY AUBREY D. P. HODGES, M.D. LOND., L.R.C.P. LOND., M.R.C.S. ENG.,
MEDICAL OFFICER TO THE UGANDA PROTECTORATE.

SLEEPING SICKNESS has been known in West Africa since 1803. Our knowledge of the origin of the Uganda epidemic is very vague. Though many natives date its beginning from 1896 it did not become known to Europeans until 1900. The fact that the natives of Uganda were not acquainted with it is no proof that former epidemics have not occurred, for they have no written records, their memories are short and inexact, and their ideas of the lapse and computation of time are rudimentary. It is quite possible that the disease is endemic in certain spots and becomes epidemic only under conditions favourable to it which may sometimes recur after long intervals. It is also quite possible that when more epidemic areas have been worked out and the organic cause has been more firmly established endemic patches may be found to exist from the great lakes to the West Coast of Africa. One of the greatest difficulties in the study of sleeping sickness has always been the extraordinary duration of the incubation period. It was long ago surmised, from cases which occurred among slaves who had been to the West Indies from Africa, that as long as seven years might pass before the disease manifested itself, while, from cases observed in Uganda, it seems certain that one or two years may elapse. Such a long and uncertain period, combined with the slow course of the disease itself, which may probably occupy any time from two months to two years, renders the scientific study of cases most difficult and in the vast majority of cases impossible. To this must be added the extreme difficulty of identification of most African natives when under intermittent observation only.

Sleeping sickness attacks all ages and both sexes but infants usually escape, and old people, who are not themselves numerous among African natives, are perhaps less liable. As was formerly pointed out by myself[2] children under three years of age rarely show the disease, the reason possibly being that they are kept more in the houses and villages and so are less exposed to infection. But the long period of incubation or latency must also be borne in mind, for it is conceivable that infection during infancy might frequently not result in sleeping sickness until early childhood. The malady does not seem, however, to attack all classes equally. The higher chiefs seem less liable to it and Europeans have remained almost immune, probably in both cases for similar reasons. As might be expected from its long incubation and slow course the onset of the disease is most insidious. It is practically impossible to say, with regard to any given case, on what exact date the symptoms commenced, while even approximate dates are difficult to verify. No doubt some sudden nerve crisis, such as a fit or an attack of mania, may sometimes draw the attention of the patient or his friends to his condition and often a period of days, weeks, or months will be given on inquiry for the duration of the symptoms, but it always remains very doubtful for how long previously the patient may have been ailing.

---

[1] Abstract of a paper read before the Islington Medical Society.

[2] Journal of Tropical Medicine, Oct. 1st, 1902.

Clinically the course of sleeping sickness has been, for convenience, divided into three stages, but their limits are very ill-defined. They are (1) the early stage, (2) the pronounced stage, and (3) the lethargic or somnolent stage. There is also sometimes an intermediate stage of nerve crisis, excitement or exhilaration, which occurs usually at the beginning of the second stage and is really a part of it. Probably the earliest subjective symptom is a chronic persistent or intermittent headache with lassitude and this may be accompanied with, or replaced by, vague pains in the back, chest, or "all over." With regard to objective signs pyrexia, if constantly looked for, may practically always be detected. From the first there is a general enlargement of the lymphatic glands, in which glands from the size of a filbert to that of a hazel-nut are found in most or all of the superficial groups, those of the neck being the most constantly affected. One of the earliest signs usually noted is an arhythmical, jerky, or twitching tremor of the tongue. There may also be an alteration of mental attitude or habits which, however, is often noticeable only by relatives or associates of the patient. As none of the above symptoms, unless it be the tongue twitching when well marked, is in any way pathognomonic it is to a combination of them that one must look for a diagnosis in the early stage. A conjunction of chronic headache or pain with lassitude, tongue tremor, and glandular enlargement is always very suspicious in a person who has visited an epidemic area, and if there is also evidence of change in disposition or if there is recurrent pyrexia the diagnosis becomes almost certain. Another early, though less early, symptom is a more or less general pruritus, of which there may be evidence in the *form of scratch-marks or small sores but which is not* [illegible] soon there [illegible] ed at first [illegible] behaviour are generally normal, at least while under medical exa- [illegible] ation, and diagnosis may [illegible] one sees the more difficult [illegible] agnosis in patients exhibiting symptoms of the early stage.

In the second or pronounced stage the diagnosis becomes almost always easy and certain. As a rule, it may be dated from the characteristic alteration which begins to take place in the patient's facial expression and general appearance, often accompanied by a change in his manner, habits, or disposition. This stage, however, is not infrequently ushered in by nervous crises such as epileptiform fits, attacks of mania, melancholia, or dementia, or by a state of exhilaration during which the patient has very much the appearance of being under the influence of alcohol. The duration of these nerve crises is generally short relatively to the duration of the disease, but they may recur or be continued into the later stages. During their continuance the patient often suffers from, and may complain of, sleeplessness. Very early in the second stage, if not frequently before, sexual impotence occurs in males though there is occasionally an outburst of excitement during the phase of exhilaration or mania. In women the menses cease early, often indeed before they have noticed any signs of illness, so that one is tempted in such cases to antedate the alleged time of onset of the disease by the period of duration of amenorrhœa. With the development of the second stage tongue twitching becomes more marked and tremor begins to spread to the cheeks and lips and to the body generally. In some cases, especially children, choreic twitchings, occasionally general but more often confined to the face and the arms, will be observed, and they might perhaps more properly be included among the nerve crises above enumerated. The muscles become flabby, the face begins to lose its expression and the limbs their strength; the speech often becomes mumbling and the articulation blurred. Fibrillary tremor becomes visible in the tongue, [illegible] The eyes get a vacant, stolid, [illegible] ie vague pains about the head, [illegible] ad are sometimes severe. Soon there is disinclination to move or to speak and inability to fix *the attention for any length of time.* There may now be signs of muscular wasting but this occurs late as a rule and even then not invariably, a good deal depending on the patient's ability to obtain food. At length there is a tendency to sleep at all hours and the patients pass surely but gradually into the last or lethargic stage which has been so graphically described and in which they eventually die, sometimes suddenly but nearly always very slowly, so that the vital functions seem to dwindle away gradually.

As occasional symptoms in the last stage may be mentioned a movement of thumb and finger or fingers, generally of one hand only, resembling paralysis agitans but not truly rhythmical, also athetosis, convulsions, ptosis, and conjugate deviation of the eyes with a movement resembling nystagmus. A troublesome stomatitis or marginal ulceration of the gums is common at almost any stage and if cured may recur again and again, but it is not to be regarded as a part of the disease.

In the first and also in the second stage there may occur, as was formerly pointed out by myself,[3] intermissions or remissions of the symptoms which may be of considerable duration—occasionally even months—but which tend to grow shorter as the disease progresses. During these intervals symptoms almost or entirely disappear so that the patient may seem, to casual observation at any rate, quite well. Even in a well-advanced stage patients may be sufficiently roused for their appearance and behaviour to present little abnormal to an ordinary examination.

On surveying the symptoms broadly two facts stand out fairly clearly: first, that they are to a great extent intermittent in character and not steadily progressive; and, secondly, that on the whole the nervous symptoms are secondary to the general, a fact which points to a general infection rather than a local disease.

The chief pathological evidence of general infection is the constant enlargement of lymphatic glands in all, or nearly all, the groups, both superficial and deep, while a chronic [illegible] ability the [illegible] this lesion [illegible] Mott and confirmed by other observers. At present, however, they have not been described as occurring in inoculated animals and the question may still be considered open as to how far they are to be connected with the various organisms which are being studied in causal relation to the disease and even how far they can be considered as the actual and necessary cause of death, or of the whole of the nervous phenomena associated with sleeping sickness.

The two organisms which are at present being studied in connexion with [illegible] described by th [illegible] of West Africa [illegible] panosome discovered by Castellani, of which the importance and universal presence in sleeping sickness in Uganda were worked out by Bruce. The trypanosome occurs not only in the blood but in the cerebro-spinal fluid in sleeping sickness, which thus differs from the condition at present known as trypanosomiasis, in which *the organism is found* in the blood only.[4] There seems to be no doubt from Bruce's investigations that at any rate the chief carrier of the trypanosome is glossina palpalis, a tsetse fly the distribution of which in the Uganda Protectorate corresponds roughly with the epidemic area. Whether this correspondence exists in other epidemic areas is not yet worked out.

Inoculation experiments by Bruce, in which the inoculations were made respectively with the blood or cerebrospinal fluid of sleeping sickness, the blood of trypanosomiasis, by the bites of fed flies and of wild flies, have produced trypanosomiasis in monkeys (cercopithecus), some of which have died, always after a period of months, in a condition clinically resembling sleeping sickness, and the macroscopic appearances at the necropsies have appeared to be identical with those seen in sleeping sickness.

How the diplo-streptococcus finds entrance to the human body is not at present known but it is pretty constantly found. The Portuguese Commission found it in 52 per cent. of the cerebro-spinal fluids which they examined and in many of the negative cases it was present in other organs. It has been found in various tissues, rarely in the blood, but, as far as I can learn, in no case yet more than six months before the fatal ending. It is found in large numbers in the microscopic brain lesions. It has not produced in animals by inoculation symptoms resembling sleeping sickness but causes death by acute septicæmia in from two to four days in rabbits and other small animals and in from one to three weeks in the cercopithecus. Its presence has not so far been recorded in those animals which have died with symptoms of sleeping sickness after inoculation with trypanosomes. It is considered, however, by some of the most competent observers engaged in the matter to be in some way intimately associated with the disease, with the microscopic brain changes, and with the fatal ending.

[3] Loc. [illegible]

[4] Since this paper was written [illegible] as occurring more plentifully i [illegible] both in trypanosomiasis and in [illegible] observation is thought to be developing some of trypanosomiasis under observation is thought to be developing some signs of sleeping sickness. Greig and Gray: THE LANCET, June 4th, 1904, p. 1570.

Taking the disease as a whole, and especially from a clinical point of view, the hypothesis of trypanosome causation would seem to cover more of the facts. The areas of distribution, so far as at present known, the distribution and habits of glossina palpalis, the comparative immunity of Europeans and apparently of the better class natives in infected areas, the fact that the disease appears to be incommunicable outside these areas, the long incubation, the course and the apparently invariable fatality of the disease, the greater resemblance to sleeping sickness of the malady produced in inoculated monkeys as compared with the acute septicæmia produced by the coccus—all these facts seem to favour the hypothesis of initial trypanosome infection; whereas some, at least, such as the long incubation and duration, the invariable fatality, the comparative immunity of Europeans and the impossibility hitherto of producing a disease analogous with sleeping sickness in animals, appear to tell rather against a streptococcal etiology, though they do not, of course, exclude the possibility of an association or secondary infection with the streptococcus being of the greatest importance to the course of the disease. The analogy of sleeping sickness with nagana is surely nearer than that with any streptococcal infection known. I have been unable to learn, however, that nagana ever occurs in epidemic form among indigenous animals as sleeping sickness does among indigenous natives.

In Sir Patrick Manson's classic case of trypanosomiasis in a European lady who died only a few months ago in which the history was well established and in which trypanosomes had been present from the first, sleeping sickness at length after two years developed in an unmistakable form. The streptococcus was found in the cerebro-spinal fluid and the tissues after death but it was probably present for some time previously and may even have been acquired before the patient left Africa. It seems from this case, however, quite reasonable, in the present state of our knowledge, to assume the hypothesis that the trypanosome is the initial cause of the disease and to suppose that there may be a more or less prolonged febrile or latent stage of trypanosomiasis which may end in sleeping sickness if the organism finds its way into the cerebro-spinal system.

In the case of native Africans we have been able neither to fix the date of inoculation nor to trace a history of initial pyrexia in cases of sleeping sickness, though a certain number of cases of trypanosomiasis remain under careful observation. As has been mentioned above, pyrexial attacks, often very slight, may probably always be recognised very early in the disease if there is the opportunity of looking for them. In Europeans one could, as a rule, obtain a history of precurrent febrile attacks by careful inquiry but in the case of natives it has proved so extremely difficult to obtain any trustworthy information that it remains quite possible that they do occur. In none of the natives with trypanosomiasis whom I have seen has the pyrexia or illness been severe, nor, beyond the fact that they have felt ill for a day or so, would they be able to tell much about it even shortly afterwards.[5] They do not recognise pyrexia as such. They may feel heat, cold, pain, or weakness but will often deny having fever even with a high temperature. To a slight or moderate febrile attack, to anything but a severe or prolonged illness, they would attach little importance, while, if it had occurred several months, or even weeks, before sleeping sickness they would not connect the two even if they remembered it.

As to whether trypanosomiasis must necessarily and inevitably pass into sleeping sickness, there is some slight reason to believe and to hope not. In the conditions in which many groups of natives live it would seem quite impossible for any of them to escape repeated inoculation and yet a few, in many cases at any rate, have so far escaped death. From this it may be hoped that the trypanosome may in certain circumstances die out in the blood; that those conditions which are favourable to its reaching and inhabiting the cerebro-spinal system and which may perhaps include association with, or secondary infection by, the streptococcus may never occur. The outlook at present is far from promising. There is no curative treatment known which is of any value. The prospects of exterminating the trypanosome or the fly are so far hopeless and it may prove that we have also the streptococcus to deal with. We may be able, however, to control the numbers and action of the fly to some extent. We already know much of its habits and the localities which it affects. Roughly speaking, it may be said to haunt jungle only—shady places with thick undergrowth, preferably near water—and not to move far from its haunts. It does not seem to penetrate into large open villages or clearings. It is not usually seen in decently hoed native gardens or plantations, nor does it occur in European settlements. It can, then, to a certain extent, be avoided.

The reasons why there is such a marked relative immunity for Europeans are probably: 1. Their manner of clothing leaves exposed a less area of skin than that of the natives and only the more sensitive parts, the hands and the face. 2. They do not live, or lie asleep in the day-time, nor do they usually work, in jungle or forest. They are less liable to get bitten and, when they do, they are more likely to brush off the fly before inoculation has been completed, for the insertion of the proboscis of the fly is easily felt, like the prick of a needle.

A systematic clearing, then, of the usual places of living and working, of the villages, watering places, landing places, &c., of the natives and the removal of the sick into open spaces would do much to diminish the risk run by the majority, especially the women and children. The more they aggregate into large villages and clearings and the less they live like animals in uncleared jungle the less likely they will be to be bitten by the tsetse fly and though, of course, some occupations, such as fishing or wood-cutting, will always be dangerous, the smaller number exposed to infection the less probability will there be of the occurrence of widespread epidemics. In the immunity of Europeans lies the best hope for the native.

Uganda.

THE SYMPTOMS AND TREATMENT OF THE INTRACRANIAL COMPLICATIONS OF OTITIS MEDIA; WITH CASES.[1]

BY GEORGE HEATON, M.A., M.B. OXON., F.R.C.S. ENG.,
HONORARY SURGEON, GENERAL HOSPITAL, BIRMINGHAM, ETC.

CHRONIC suppurative inflammation of the middle ear is a disease of such great frequency and is liable to such a variety of complications, some of them of minor import but some of them fraught with extreme risk to life, that its study is of interest to all medical practitioners. The study of the disease itself, its minor complications and treatment, would alone occupy more than the limited time at my disposal to-night even were I in a position to throw any fresh light on the subject, and I shall not essay the task in the presence of professional colleagues who are better qualified than I to do so. But when the disease spreads beyond the temporal bone and invades the cavity of the cranium complications may arise which call for immediate and sometimes heroic surgical measures, and it is of these that I wish to say a few words. Upon a prompt recognition of their symptoms the patient's life may often hang and the busy practitioner who forms an early diagnosis has as great a part in saving the patient's life as the operator who successfully deals with the case with the knife. The tardy recognition of a meningitis which has become general or of a septic thrombosis when the lungs are riddled with abscesses is practically of no value except for prognosis, for operation is then an almost hopeless proceeding and, in fact, only tends to bring discredit upon surgery.

The three intracranial complications which are of greatest frequency and importance are: (1) Intracranial abscess either between dura mater and bone or in the cerebrum proper and cerebellum; (2) thrombosis of the sigmoid portion of the lateral sinus; and (3) septic meningitis But it must be remembered that any two of these complications or even all three may be present in a single case. The shell of bone which separates the tympanum and its accessory cavities from that of the cranium is in places so thin that it is a matter of some wonder that brain complications are not more frequent than they are in middle-ear disease But that the risk of life is a real and serious one is shown by the fact that few, if any, of the better-class insurance companies will accept the life of a proposer with any active middle-ear disease without an almost prohibitive addition to his premium Such complications are more frequent in childhood than in adult life, partly because the petrous bone in childhood is thinner than in after years and partly because acute otitis media most commonly commences in childhood and the risk of extension is, of course, greatest while the disease is most active

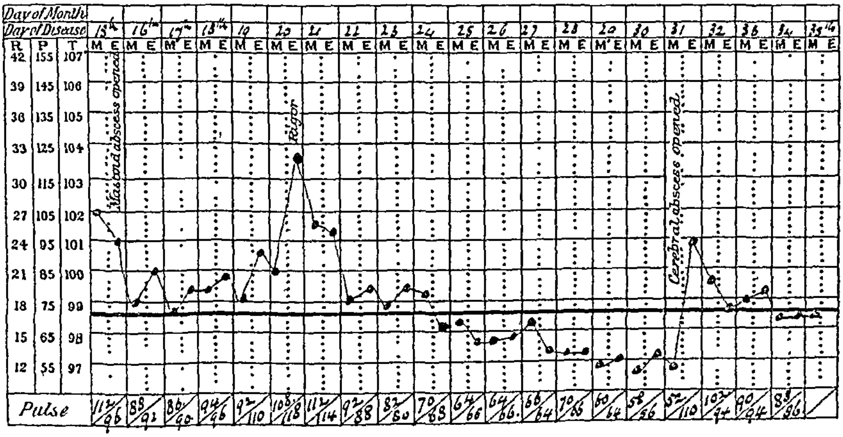
---

[5] Loc. cit.

[1] A paper read before a meeting of the Post-Graduate College on June 20th, 1904.

In order as much as possible to avoid repetition and to limit my remarks to the hour at my disposal I will discuss [illegible] nplications, [illegible] ce [illegible] be remembered that there may be no visible ear discharge in these cases Even when the otorrhœa has previously been profuse it frequently ceases or becomes much diminished on the onset of cerebral complications Amongst the poorer and less observant class of patients, no discharge may ever have been noticed, and this occasionally throws the practitioner off his guard Where present, the discharge is usually extremely fœtid and the same fœtor is often present in the patient's breath, his excreta, and in the pus which is evacuated from the brain or lateral sinus In a doubtful case an examination of the ear should always be made. After cleaning the external meatus of inspissated pus or cerumen, a perforation will then almost always be discerned in the membrana tympani or the membrane may be found entirely destoyed. Cases, however, of cerebral abscess have been recorded following middle-ear disease where the membrane was still intact.

Pain.—Pain is usually the first symptom complained of in all these cases It is "boring" or "shooting" in character, and is usually one-sided. It is often agonising and apt to come on in paroxysms. The intensity of the pain and its usually one-sided character help us to distinguish sinus thrombosis or cerebral abscess with typhoid abdominal symptoms from enteric fever in which the headache is a more general one and is not so prominent a symptom The pain usually remains a prominent symptom throughout the case or as long as the patient retains his consciousness As coma supervenes in the later stages of cerebral abscess or meningitis the sensibility becomes impaired, but in sinus thrombosis it often remains until the end.



Tenderness.—With the pain there is usually great tenderness over the mastoid and temporal regions, in fact, the whole side of the head is often acutely tender to the touch. Such tenderness may of course be due to suppuration limited to the mastoid cells and antrum or to a sudden lighting up of mischief in the middle ear But in these cases the tenderness is more limited in its area and is soon followed by œdema of the tissues over the mastoid process, the ear itself being pushed forwards and downwards When the lateral sinus is involved if the skin behind the ear be carefully and systematically palpated an exquisitely tender point may sometimes be elicited which corresponds with the exit of the mastoid emissary vein from the skull This is a very significant symptom when present and attention has been called to it by my colleague Mr. L. P. Gamgee In the later stages of sinus thrombosis when the infective process has extended to the extracranial portion of the jugular vein swelling and tenderness appear in the upper portion of the posterior triangle of the neck and spread downwards along the course of the vein In doubtful cases, where it is difficult to say on which side the brain trouble is, percussion of the two sides of the head is sometimes of value, the patient wincing when the affected side is tapped

Rigors and vomiting.—These frequently herald the extension of the disease from the bone to the brain. Such rigors do occasionally occur when only the mastoid antrum is involved But the occurrence of a rigor in a case of ear disease is always of grave significance and should in any case be followed by an operation on the antrum if such has not already been made In some cases the rigor is slight, particularly in cerebral abscess, and it may pass unobserved. It is frequently called a convulsion by the patient's friends. They are most frequent in sinus thrombosis and are usually a marked symptom throughout the disease, occurring at intervals of two or three days and each one followed by profuse perspirations—in fact, being the typical rigors of pyæmia In septic meningitis they occur at irregular intervals Vomiting without any gastric disturbance is also an early symptom and continues at irregular intervals throughout the course of cerebral abscess and meningitis. It occurs also in sinus thrombosis but is not so prominent a symptom. Complete anorexia and rapid wasting with vomiting are very suggestive of abscess formation in the brain and are particularly prominent symptoms when the pus is forming in the cerebellum

The temperature, *pulse*, and *respiration* are liable to extreme variations and vary much in the course of the particular complication. In cerebral abscess forming slowly and without meningitis, the temperature after the first initial rise has a tendency to fall and gradually become subnormal At the same time as the abscess enlarges and the intracranial pressure increases the pulse and respiration also fall in frequency The pulse is slow, often soft rather than full, and may fall as low as 35 or 40 The respiration falls with the pulse and in cases unrelieved by operation actually stops some time before it. These changes in pulse and respiration are most marked in abscess of the cerebellum, The respiration in these cases may be Cheyne-Stokes in character and the pulse extremely slow. When, however, the abscess is of quick formation, and accompanied by meningitis and encephalitis of the surrounding brain tissue, both temperature and pulse may continue high, but even then as the case progresses both show a tendency to fall. (See chart.)

The temperature chart in sinus thrombosis is usually quite typical. It is a high one with marked remissions between the rigors. During these the temperature may rise as high as 105° or 106°. It seldom, however, falls to normal between them and when septic emboli have formed in the lungs the remissions become less marked. The pulse varies with the temperature. During the rigors it may be almost uncountable and then fall to between 80 and 90 afterwards. The respirations at first vary with the temperature but when the lungs become involved gradually merge into the shallow, painful. catchy breathing of pneumonia. The occurrence of stitch-pains in the side and difficult painful respiration in the course of a case is always a dire omen and is soon followed by the expectoration of the characteristic "prune juice" fœtid sputum, with local patches of dulness over the bases of the lungs and other evidences of breaking-down pulmonary infarcts.

In meningitis the temperature is irregularly high (from 102° to 104°) but does not show the marked remissions of sinus thrombosis. The pulse remains consistently rapid and as the fatal issue approaches frequently cannot be counted. The breathing is usually rapid but where the base is much involved may be Cheyne-Stokes in character. The bowels are usually constipated in meningitis and cerebral abscess, while diarrhœa with very fœtid stools is often present in sinus thrombosis.

Appearance and odour of the patient.—During the progress of a case of cerebral abscess the patient rapidly emaciates and his complexion usually becomes of a peculiarly sallow earthy tinge. A yellowish tinge is sometimes present in sinus thrombosis but neither is characteristic. There is often a peculiarly offensive odour about these patients, their mouths, breath, and excreta generally having exactly the same smell as the pus which is afterwards liberated from the cerebral abscess or infected sinus. In cases of sinus thrombosis where abscesses have formed in the lung the smell is generally abominable and putrescent and may necessitate the isolation of the patient.

The intellect and senses.—In a typical case of cerebral abscess, as the pus forms and pressure increases, the cerebral processes become slower and duller. The patient at the commencement shows a decreasing interest in things around him and an increasing forgetfulness. These symptoms are soon followed by a drowsiness from which it becomes more and more difficult to rouse him. In this state he remains oblivious of any wants, though he can generally be roused for a few moments to take food or when loudly spoken to. There are at the same time rapid failure in the muscular power and wasting of the muscles. As the abscess increases in size this drowsiness deepens into actual coma from which he cannot be roused by any stimulus. In this stage there is usually involuntary passage of urine, or sometimes complete urinary incontinence, and the urine frequently contains albumin which may disappear after evacuation of the abscess. In sinus thrombosis the contrast is a complete one. In the absence of a complicating meningitis the intellect is often unclouded and the senses are undimmed to the very last. I have in one or two cases noticed a peculiar hypersensitive state of the patient with a tendency to chatter about himself which is quite characteristic of this disease. When meningitis supervenes on abscess or sinus thrombosis these symptoms are masked by those of meningitis and partial or complete coma quickly sets in.

Eye changes.—When abscess of large size exists in the temporo-sphenoidal lobe it may produce complete paralysis of the third nerve on the same side by direct pressure causing ptosis, immobility of the eye, with an external squint and dilated and fixed pupil; when the abscess is small the pupil is usually small and sluggish in its action to light. There is usually optic neuritis in both cerebral abscess and meningitis and in the former it is sometimes most marked on the side of the abscess. In meningitis the pupil changes are usually bilateral and the neuritis is intense. In uncomplicated sinus thrombosis there are no changes in the pupil and, as a rule, no optic neuritis.

Muscular paralysis.—Temporo-sphenoidal abscess when of large size may cause hemiplegia or paresis of the muscles on the opposite side of the body, the facial muscles being most affected. This must be carefully distinguished from the facial paralysis sometimes present from direct implication of the nerve in the disease, as it lies on the aqueductus Fallopii. The paralysis in this case is a complete one and on the same side as the abscess. Sensory aphasia has occurred in several nervous cases of temporo-sphenoidal abscess from direct pressure on Broca's convolution. It is generally difficult, owing to the mental condition of the patient, to detect slight paralyses, but in such cases the dynamometer may give valuable help. In sinus thrombosis there are no characteristic paralyses.

Chest signs and symptoms.—These are of little clinical importance in abscess and meningitis but of the gravest importance in thrombosis. The emboli carried into the blood-stream usually lodge in the minute pulmonary blood-vessels and set up multiple small pyæmic abscesses. The embolism, as a rule, takes place about the second or third week. The earliest signs are often a "stitch" pain in the side and a short hacking cough. These are soon followed by the appearance of scattered patches of dulness over the bases of the lungs. The consolidated patches quickly break down and the patient coughs up the characteristic fœtid "prune-juice" sputum. Unfortunately, when the lungs have become involved surgery has little chance of success and operation on the sinus is generally too late. In other cases the systemic infection seems to cause a train of abdominal symptoms. Frequent vomiting, with abdominal distension and pain, sets in and continues. The stools are loose and often there is profuse diarrhœa, the stools having the characteristic fœtid odour of the breath and ear discharge. Together with these symptoms there may be enlargement of the spleen. These cases are frequently mistaken for typhoid fever which they closely resemble. There are, however, no characteristic rose-spots but perhaps a dull-red, general, mottled rash and the blood does not give the Widal reaction. There are in addition the head and ear symptoms and the headache is much more severe and often unilateral. There are certain other local signs of thrombosis which in doubtful cases may assist in the diagnosis and which may be alluded to here. In a considerable proportion of the cases the soft tissues over the mastoid, besides being tender, are also œdematous. As the thrombosis extends down the internal jugular vein there will be pain and tenderness below and in front of the mastoid process and the thrombosed vein may actually be felt as a hard tender cord. The deep lymphatic glands and soft tissues around the vein soon become inflamed and swollen. Pus will eventually form around the vein and point in the neck below the mastoid process. The pain and tenderness in the tissues of the neck cause stiffness but usually the actual retraction of the head, so characteristic of meningitis of the base, is absent. The mastoid emissary vein may be distended or thrombosed. The acute tenderness over it I have already alluded to.

The prognosis in all the intracranial complications of middle-ear disease is a grave one. General septic meningitis is the gravest of the three. Personally I doubt whether in any case where the meningitis has become a general one has the patient ever recovered; nor do I think that surgery at present holds out any chance to the patient. When the pus formation is localised and the abscess forms between the dura mater and the bone the prognosis is much more hopeful; such abscesses may even discharge themselves through erosion in the bone into the tympanum. I have published such a case and many others are on record. Cerebral abscess usually proves fatal in a few weeks. Rare cases have been recorded where the abscess has become encysted and ultimately absorbed. But this, however, rarely if ever happens where the abscess owes its origin to ear disease. On the other hand, there is no cerebral affection in which surgery has shown such brilliant results. Probably quite two-thirds of the cases of abscess above the tentorium undergo complete recovery after free evacuation and drainage. The prognosis of cerebellar abscess after operation is more grave than that of abscess in the temporo-sphenoidal lobe. The pressure symptoms on the delicate structures at the base of the brain are more rapid and severe and the risk of meningitis after operation is greater.

Infective thrombosis of the lateral sinus if unrelieved is almost invariably fatal. Post-mortem examinations, however, do occasionally reveal a lateral sinus which has been obliterated many years before death, where from the presence of old-standing ear trouble the process has in all probability been an infective one. But the micro-organisms cannot in such cases have invaded the thrombus. In THE LANCET in 1861 P. Hewitt reports a case where after apparent involvement of the lungs recovery eventually took place. If systemic infection has not already occurred operation holds out a reasonable prospect of recovery. But when the lungs are already involved surgery is almost powerless. *Nevertheless, an attempt should be made* to shut off and to remove the source of the infective emboli.

Treatment.—Various operations have been devised by surgeons for the relief of intracranial abscess and sinus thrombosis, the object in the one being the detection, tapping, and efficient drainage of the abscess, and in the other the opening and complete cleansing and drainage of the infected sinus. Into the details of these various operations I do not propose to enter, but I wish briefly to touch upon the operation which I carry out in these cases and which has never failed in my hands to discover the pus when present.

The entire scalp should be shaved the day before the operation when this is [illegible] it is [illegible] wards [illegible] y and [illegible] litory [illegible], all [illegible] the [illegible] These processes should all be repeated on the operating table. If the patient is still conscious chloroform is the best anæsthetic as it causes less cerebral congestion. But a most careful watch must be kept upon both the pulse and respiration throughout the whole operation, the respiration in particular being liable to fail and to stop when the intracranial pressure is great, especially when abscess is present in the cerebellum. When the patient has already lapsed into a state of coma no anæsthetic will be needed or at most a few [illegible] chloroform to dull the pain of the skin incision. [illegible] incisions are recommended and different author[illegible] widely differing landmarks for the exposure of th[illegible] antrum, the lateral sinus, and the brain (above and below the tentorium). I shall only mention the one which I usually employ and with which I have every reason to be satisfied.

The first stage in the operation is to open the mastoid antrum and to lay its cavity freely open into that of the middle ear. We may thus in some cases be able to trace the course of the disease backwards through the bone and to form some idea of the situation and extent of the intracranial mischief when present. To do this an incision with a slight concavity forwards is made directly down to the bone, through all the tissues of the scalp, and extending from a point on a line with the top of the pinna almost as low as the tip of the mastoid process. The soft tissues are elevated from the bone and the pinna drawn well forwards; the margins of the osseous meatus and boundaries of the suprameatal triangle under which the antrum lies are defined. By means of bone chisels and gouges the antrum is opened just above and behind the [illegible] often very much enlarged in size and [illegible] bony wall is to be removed and [illegible] cleansed. The cavity of the antrum is then laid freely open into that of the middle ear and bony meatus by chiselling through the bridge of bone which lies between the surface of the skull and the aditus of the antrum. While freely opening the middle ear and antrum it is sometimes possible to detect an erosion in the roof of [illegible] tympanum or antrum leading into the cavity of [illegible] cranium. In such a case the opening is enlarged and brain abscesses have been tapped through such erosions. A large curved flap of scalp is now to be turned down from the skull behind the first incision. This is done by making a bold curved incision, starting at the upper angle of the first incision and carrying it upwards and backwards and then downwards through [illegible] of the scalp. The flap of scalp so raised [illegible] wards with the periosteum covering the [illegible] the bone and the skull is freely exposed. [illegible] examined, the condition of the mastoid emissary vein, whether patent or thrombosed, is noted and the various bony sutures and landmarks are clearly defined. The angle of junction of the posterior inferior angle of the parietal bone with the squamous and mastoid portions of the temporal bone is particularly noted. The junction of the sutures is quite easily defined on the bared skull and is an important landmark. A line drawn from it to the [illegible] towards the jugular fossa; a trephine should never be applied in this line as the bone at the bottom of the groove is occasionally very thin.

The dura mater and brain above and in front of the sinus *are first of all to be explored. To do this a crown of bone* one inch in diameter is removed with a trephine. The centre pin of the trephine is placed—in the adult—over a point one and a quarter inches above and one and a quarter inches behind the centre of the external auditory meatus. The trephine is applied in the usual manner, and personally I prefer a trephine worked by hand in preference to any of the machine-driven or electrically driven instruments. The opening thus made in the skull is rapidly enlarged in a direction downwards and forwards with Hoffmann's bone forceps (taking care before each application of the forceps to separate the dura mater from the under surface of the skull) until the opening is continuous with that already made for cleansing the antrum. In this way there is practically no risk of inadvertently wounding the wall of the sinus, however thin the skull may be. If the collection of pus be an epidural [illegible] mater and the bone—th[illegible]. The pus is evacuated [illegible] cleansed and irrigated with some mild antiseptic. Particular care should be taken in these cases to see that suppuration has [illegible] ded along [illegible] it is very [illegible] the skull should be removed. When pus is not encountered outside the dura mater the condition of that membrane is to be noted carefully. Increased tension and absence of visible pulsation usually point to a diffuse lepto-meningitis beneath or to a localised cerebral abscess. The surface of the dura mater [illegible] with unhealthy granulation [illegible] over the sinus. By careful [illegible] to detect that the sinus is [illegible] owing to its feeling of solidity.

The next step in the operation is to explore the brain above the tentorium for pus. This may be done quite easily and thoroughly without at first opening the dura mater. The needle of an exploring syringe is passed through the dura mater into the brain substance at a point one inch above and one inch behind the osseous external meatus. It is thrust in a direction downwards, inwards, and slightly forwards, and should be directed towards the roof of the tympanum and the upper border of the petrous bone. The needle itself should be of a good size, as if small it is apt to become choked by small portions of soft brain matter. The brain may in this way be very freely explored in many places and in various directions without apparently any permanent injury being inflicted. I have on two or three occasions drawn off fluid from the lateral ventricle in my explorations. Directly pus is reached the needle should be detached from the syringe and held firmly *in situ* as a guide while the abscess cavity is reached [illegible] The dura mater is opened by a crucial incision [illegible] of sinus forceps or large trocar and cannula is passed into the abscess cavity through which the pus is allowed to escape. The pus is usually extremely offensive and has the same peculiar fœtid odour which [illegible] the ear discharge. A [illegible] passed into the ca[illegible] abscess is irrigated [illegible] and cleansed, but it must be very cautiously shortened and must not be removed until the patient's condition has become quite satisfactory and all discharge has ceased. The dura mater should be sutured loosely round the tube to prevent adherence of the brain cortex to the scalp when the flap is laid down. When the abscess has been a large one and [illegible] ranial pressure great the immediate relief of the [illegible] is often marvellous. The pulse almost at once [illegible] frequency, the respirations are deepened and quickened, and pulsation returns in the exposed brain cortex.

If the patient's symptoms point strongly to abscess of the brain and no pus is discovered after repeated exploration above the tentorium the lateral lobe of the cerebellum should be explored. An abnormally slow pulse, marked optic neuritis, rapidly failing respiration or Cheyne-Stokes's breathing, with perhaps some retraction of the head and a

A CASE OF MULTIPLE SARCOMA.

BY SEYMOUR TAYLOR, M.D. ABERD., F.R.C.P. LOND.,
PHYSICIAN TO THE WEST LONDON HOSPITAL.

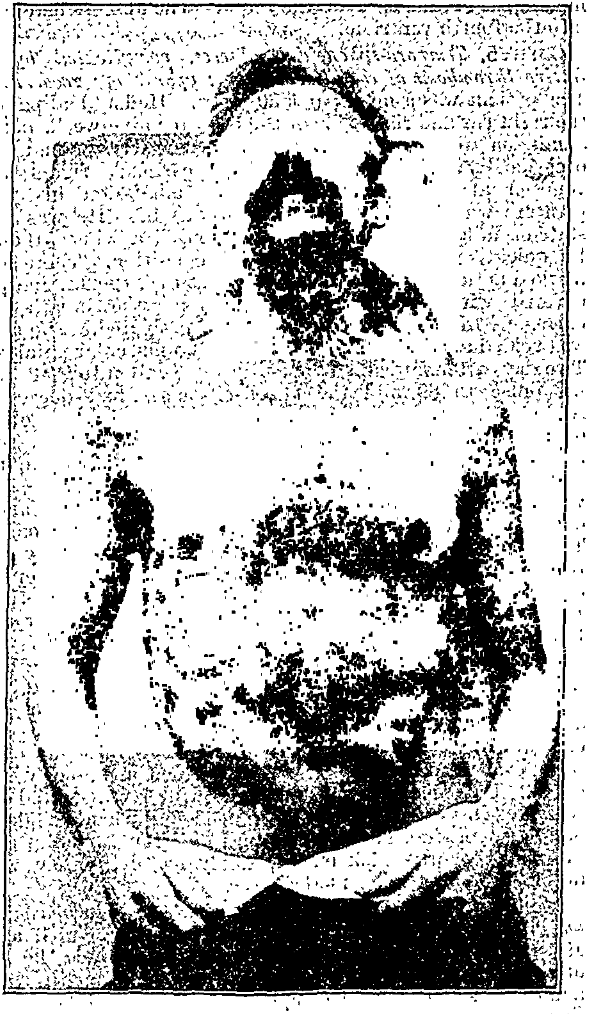
A MAN, aged 32 years, was sent to consult me on Jan. 7th, 1904, by Mr. F. E. Streeten of Swindon. The patient was in his usual good health until the previous July, when he noticed a "lump" in the abdominal wall which appeared "to have sprung up suddenly in the night." It was unattended by pain. A few days afterwards he complained of cough which had continued up to the time when I saw him but which had not been attended by hæmoptysis, or expectoration, or night sweats, although he had lost flesh considerably. Since then numerous similar "lumps" had appeared all over the trunk, back and front. There was no history of syphilis. His parents were both living and healthy and there was no family history of tuberculosis. There was no history of any previous extensive disease of the skin but a slight patch of eczema had existed over the inner left ankle for some months.

The patient was admitted into the West London Hospital and on examination he was found to be a well-made man, somewhat pallid and emaciated. When he had removed his shirt some tumours were noticed in the skin over the scapular regions. In appearance they gave one the suggestion that they were sebaceous cysts. But further examination failed to discover their porous outlets and, moreover, their consistence on digital examination pointed to their being subcutaneous new growths. On examining the front surface of the body an extraordinary condition of affairs was presented. Scattered over the abdomen and thoracic walls were a number of solid tumours, varying in size from that of a Tangerine orange (which was the first tumour the patient had noticed) to that of a large pea. The large growth was situated in the right side of the abdominal wall midway between the anterior superior iliac spine and the umbilicus, though slightly above this horizontal line. Its surface was red and granular in appearance, looking as though it was ulcerated; but there was no discharge or "weeping" of any kind, although yellowish scales of necrosed epidermis appeared between the granular nodules. On the opposite side of the abdominal wall in the corresponding site there was almost a similar lesion, the difference being that two contiguous tumours occupied the space filled by the tumour in the right side, while symmetrical growths were seen to exist between the larger ones described above and the nipples. Both mammæ were indurated and involved with the neoplasm, the skin, however, in these localities being as yet intact. Similar nodules, though not well seen in the illustration, were found in the skin over each fourth costal cartilage, and when one traced these various growths they gave one the impression of a circular outbreak which involved the abdominal wall principally, but also the lower zone of the thorax to a lesser degree. This configuration, however, could only be accidental, as other tumours were found within this zone, and I know of no condition of vessels, whether appertaining to the circulatory or to the lymphatic system, which could give origin to this annular arrangement of the tumours. Other similar growths, though not so large, only two or three being of the size of nutmegs, were found over the front of the upper chest. The lymph glands of the groin were indurated and matted together but the skin moved easily over each mass. The glands of the axillæ were similarly affected though to a less degree. Those of the neck were unaffected.

The skin was fully moveable over each tumour and was not involved over the smaller ones, but over those which had attained a large size corresponding to the bulk of a pigeon's egg the skin was reddened and glazed, whilst the superficial veins stretching over them were engorged and slightly varicose. In those which were more advanced, as in the largest tumour first described, the surface was red and granular, with necrosed epidermis scales in the fissure between the tubercular outgrowths, but there was no moisture or exudation.

Similar tumours were found on the dorsal aspect of the trunk, especially on the left scapula, but in none of them was the skin reddened or abrased.

The chest was slightly "barrel" shaped. The percussion note over the upper lobe of the right lung was somewhat impaired both back and front and there were signs of deficient air entry to this region. Fine crepitations were heard over the right apex posteriorly and the expiratory murmur over the whole of the upper lobe of this lung was prolonged and blowing. The physical signs in the other regions of the respiratory tract were healthy. In addition the patient had marked inspiratory stridor. There was slight frothy expectoration but no tubercle bacilli were discovered. A laryngoscopic examination kindly made for me by my colleague Dr. J. B. Ball showed that there was no paralysis of the vocal cords and nothing could be seen to account for the inspiratory stridor.



A case of multiple sarcoma.

The heart sounds were normal. The liver extended almost to the umbilicus and the lower part of its anterior surface could easily be felt—it was hard, nodular, and somewhat tender to the touch. The bladder and prostate gland were healthy. No evidence of ulceration or of new growth could be discovered by rectal examination. The urine was free from albumin and sugar and was quite normal in specific gravity and reaction. The bowels acted regularly. The patient complained of slight dyspnœa and cough which prevented him from sleeping and for which a linctus containing opium was prescribed.

The question of diagnosis at first was difficult to decide. The disseminated character of the growths and their rapid invasion made one think of mycosis fungoides but the absence of a history of previous extensive skin disease (although a slight eczematous patch was still to be seen over the inner side of the left ankle) and the dryness of the surface of the tumours led one to reject this diagnosis.

Acting on the supposition that the disease might be tuberculous and pending a microscopical examination of the tumours, shortly after admission half a grain of sodium cacodylate was injected subcutaneously twice a day. This caused pain in the tumours generally and this reaction continued so long as the injections were being made. But the sudden onset of the disease, its rapid spread and wide dissemination, and the secondary affection of the respiratory tract, which was proved to be non tuberculous, all tended to the diagnosis of sarcoma Meanwhile, in order to settle a definite diagnosis one of the smaller and less advanced growths was, with the patient's consent, excised, and after being duly hardened it was prepared for, and examined by, the microscope The evidence which this afforded proved that the growths were those of sarcoma of the small round-celled variety. *An unfavourable prognosis was given* and the patient shortly afterwards expressed a wish to go to his home in the country

By the courtesy of Mr. Streeten I have heard that the patient died towards the end of February, seven months after the first signs of the disease were noticed "The only fresh symptom which he had was urgent dyspnœa in paroxysmal attacks, one of which proved fatal No autopsy was allowed, though the patient expressed a wish that one should be made"

Seymour-street, W.

A CASE OF ACUTE ARSENICAL POISONING.

BY R E SEDGWICK, B A , M B , B C CANTAB ,
LATE SENIOR HOUSE PHYSICIAN AT THE GENERAL HOSPITAL, BIRMINGHAM

DEATHS from acute arsenical poisoning are sufficiently rare to make the notes of such a case and of the subsequent post-mortem examination of interest and value.

On March 24th, 1903, at 5 30 A M , I was called to see a man reported as "very ill and almost dying" On arrival at the house, 20 minutes later, I found the patient on his bed, dead He was lying on his back with his left knee drawn up and his arms extended His hands and feet were cold, as were also his nose and face, while his body was warm He was well developed and well nourished but his eyes were sunken far in their sockets and a general pinched expression on his face gave him an appearance such as is *frequently seen in a child* with epidemic diarrhœa The room was poorly furnished but clean , there were no signs or traces of vomited matter or fæces either in the chamber (which was empty) or about the floor and bed On the dressing table was a glass mineral-water bottle containing about two drachms of slightly milky fluid

The history obtained was as follows The patient, who was a labourer at a glass-works, had always enjoyed good health On March 23rd he was quite well, had his breakfast with the rest of the family (who were well), and went to work He returned home about 2 30 P M and vomited in the entry, stating that he was "bilious" He continued to retch and to vomit and was then given a bottle of "ginger beer," after which he seemed more comfortable and dozed on the sofa Shortly afterwards he had great abdominal pain, was violently purged, and again sick. He continued to be purged and sick until about 8 P.M , when he went to bed but without relief As he became so weak he was asked to *see a medical man but declined*, stating that "he didn't want one as he was going to die" At 5 A M on the next morning he became so "bad that I was sent for All inquiries led to no elucidation of the mystery and the body and the bottle of "mineral water" were removed to the mortuary by the police and the facts were duly notified to the coroner

Necropsy —On March 26th two days later, I made a post-mortem examination of which the following are the notes The body was that of a well-developed, well-nourished man, aged about 32 years, height 5 feet 9 inches It had been in the mortuary two days (48 hours). The weather was mild and damp The eyes were markedly shrunken in the sockets and the face had a pinched expression No putrefactive changes were visible and there was no post-mortem rigidity Slight venous con*gestion was visible on the buttocks. There were no external* marks of violence. The coverings and bones of the skull were normal The brain showed no venous hypostasis and the membranes were dry. The brain substances were normal; there were no hæmorrhages or ecchymoses The ventricles were dry, on section they were drier and firmer than normal The lungs were dry and crepitant, there was no posterior hypostasis At the apex of the right lung was an old scar which was [illegible]
normal , there were [illegible]
heart were empty [illegible]
in the right auricle [illegible]
ventricle , otherwise [illegible]
clean at the tip and sides , it was slightly furred at the back. The pharynx and œsophagus were normal , no redness or hæmorrhages were present The stomach contained about a pint of yellow turbid fluid in which were floating several large, whitish-yellow, opaque masses Some mucus settled on standing in which were a few green coloured particles. The external wall of the stomach was pink in colour except for about two inches along the pyloric third of the greater curvature where it was of a dusky scarlet colour The mesenteric glands along the greater curvature were enlarged to sizes varying from that of a bean to that of a Brazil nut and were soft, cherry-red in colour, and on section almost diffluent Internally the mucous membrane of the stomach was thrown into folds and was generally reddened and covered with a thin layer of slimy mucus In five or six places were patches of ecchymoses and petechiæ, chiefly lying along the greater curvature and the posterior wall, while in three places were adherent, whitish yellow, opaque masses, surrounded by an area of scarlet-coloured and reddish brown membrane, the largest and firmest of which corresponded to the scarlet coloured patch on the outer wall of the greater curvature There were no [illegible] characteristic
odour [illegible] coated with
slimy m[illegible]ally, the redness on close inspection being due to minute petechiæ The outer covering was bile stained and reddened The third part together with the jejunum was completely empty except for the mucus which, indeed, lined the whole of the intestinal tract The ileum in its lower 12 inches was slightly reddened and on one spot about eight inches above the ileo cæcal valve was a small crater-like ulcer of the size of a pea with a smooth base and a ragged, vivid scarlet edge. Two of the neighbouring glands were swollen, soft, and red The large intestine was empty , there was no trace of ulceration The liver was normal in appearance, it was dry on section. The gall bladder was empty The pancreas and spleen were normal Both kidneys were normal in appearance The capsules stripped easily The kidney substance was apparently healthy on section A few rather bright red [illegible]
the pyram[illegible]

An inque[illegible]
of the stomach contents, &c At an adjourned inquest held on April 28th inquiry elicited that the man, an agent for an insurance society, was in monetary difficulties and had been threatened with legal proceedings He had also been seen standing near a barrel of ready-mixed "frit" (which contained arsenic) *at the works about 11 30 A M He also* vomited about noon and once or twice between noon and 1 P M , when he left work.

Mr H Silvester, public analyst of the county borough of West Bromwich and Dudley, reported as follows —

1 *Contents of stomach* —One pint. Arsenic was present to the extent of 2 17 grains expressed as arsenious anhydride (As_4O_6)

2. *Portion of liver* (weight eight and a half ounces) —The portion of liver contained arsenic equivalent to 0 45 grain of arsenious anhydride

[illegible] duly contained arsenic

[illegible] as as follows Stomach [illegible] grain , and left kidney,

Carlisle

WIGAN MEDICAL SOCIETY.—A meeting of this society was held on July 14th In the absence of the President Dr Blair was voted to the chair After the ordinary business a paper was read (illustrated by lantern slides) by Mr Robert Jones on Injuries about the Elbow-joint The paper and the illustrations were very interesting and a discussion followed in which the following members took part Dr White, Dr Rees, Mr Brady, Mr Bowen, Mr. Graham, and Dr Blair A cordial vote of thanks was unanimously accorded to Mr. Jones for his paper.

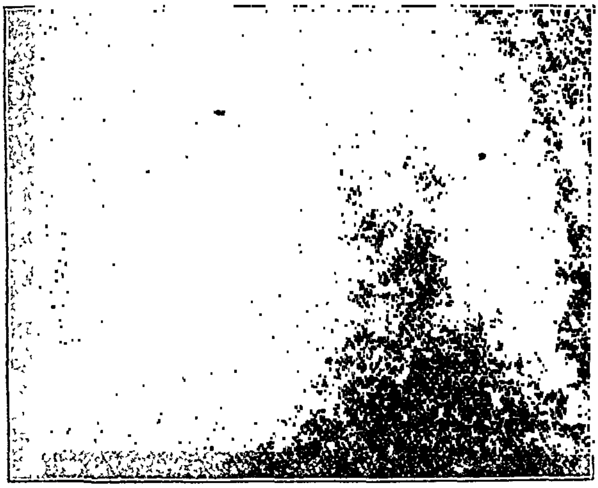
Clinical Notes:
MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF TRAUMATIC PNEUMOTHORAX WITH SLIGHT SYMPTOMS.

BY R. STANLEY TAYLOR, B.A.,
ROENTGEN RAY ASSISTANT AT CHARING CROSS HOSPITAL.

THE patient, a boy aged six years, was taken to the hospital on Feb. 16th, 1904, with the history of having been knocked down and run over by a cab. There were a large scalp wound over the left occipital region and a superficial abrasion over the anterior ends of the right fifth and sixth ribs and costal cartilages, which were also somewhat tender on palpation but no definite evidence of fracture could be discovered. His respirations were a little laboured, varying from 36 to 40 to the minute; his colour was perhaps a trifle dusky and he had an occasional dry cough.

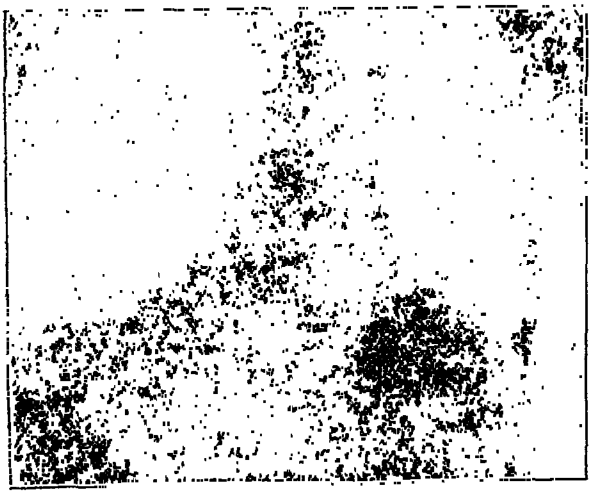
FIG. 1.



Skiagram showing appearance caused by collapsed lung.

The chest was not carefully examined at the time of admission but on the second day after the injury, when the first skiagram was taken, examination of the chest showed on the right side practically no expansive movement, very much diminished tactile fremitus, hyper-resonant percussion note everywhere, that below the clavicle being particularly tympanitic, and weak breath sounds of an amphoric quality. A satisfactory bell note could not be obtained. The left lung was normal. The apex beat was situated in the nipple line in the fourth space and cardiac dulness extended from this to the left sternal border, the heart being little, if at all, displaced. The heart sounds were normal.

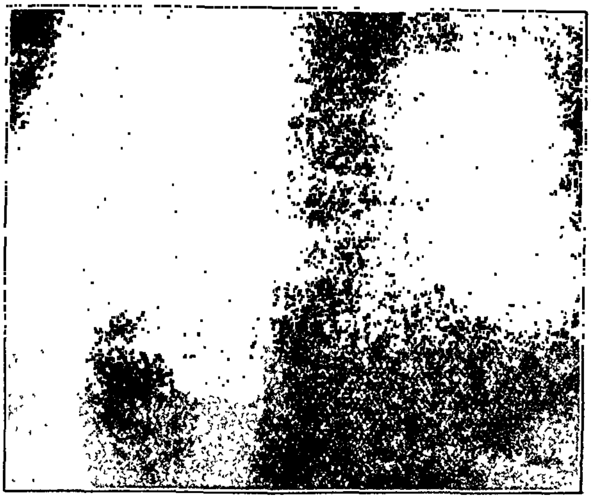
FIG. 2.



Skiagram showing lung to have increased in size.

A skiagram taken on Feb. 24th (Fig. 1) showed the whole of the right chest to be abnormally transparent to the rays with the exception of an area of the size of a Tangerine orange opposite the second and third spaces, presumably caused by the collapsed lung. The symptoms disappeared in a few days and he, except for his head injury, did not appear to have anything wrong. The lung, however, took a considerable time to expand, although a definite increase in its size was shown by a skiagram taken on March 10th (Fig. 2). A third skiagram taken on March 22nd (Fig. 3) showed the lung to have expanded over the whole right side of the chest and the normal physical signs were restored. The patient was discharged quite well on March 24th.

FIG. 3.



Skiagram showing expansion to have been restored.

The case is unusual in being one of traumatic origin, involving total collapse of the lung, but in which the concomitant symptoms were comparatively slight. The absence of any definite signs of fracture suggests the possibility of the condition being produced solely by rupture of the visceral pleura.

The x rays proved a valuable adjunct in diagnosis and the subsequent expansion of lung and absorption of air from the pleural cavity formed interesting subjects for the second and third skiagrams.

I am indebted to Mr. J. H. Morgan for permission to publish the notes of the case.

Charing Cross Hospital.

NOTE ON A CASE OF CÆSAREAN SECTION FOR RENIFORM RACHITIC PELVIS.

BY J. B. C. BROCKWELL, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT MEDICAL OFFICER, POPLAR AND STEPNEY SICK ASYLUM.

A MARRIED woman, aged 22 years, a primipara, was admitted into the Poplar and Stepney Sick Asylum under my care on June 25th, 1903, at 4.30 A.M. Labour had commenced at about 6 P.M. on the previous evening, but the pains had ceased shortly before admission. On examination the patient was very short in stature (4 feet 3½ inches); the tibiæ were short and very curved with the convexity forwards; there was marked scoliosis with a dorsal curve the convexity of which was to the right; and the sacrum was depressed leaving a marked depression between the ilia. The external pelvic measurements were as follows: (1) distance between the anterior superior iliac spines, 10¾ inches; (2) distance between the widest points of the iliac crests, 11 inches; and (3) external conjugate, six inches.

The diagonal conjugate measured three and one sixth inches, two and a half inches at the most further examination per vaginam rum could be felt forming a projection *encroaching on the space of the pelvic brim*. The os uteri could only be reached with difficulty and was of about the size of a shilling and the fœtal head could with difficulty be made out above the brim.

As there had been no return of the labour pains and as the os was quite small it was decided to leave the patient to get a few hours sleep. I saw her again at 10.30 A.M. when the pains had just recommenced, the os had further dilated and a long bag of membranes was protruding through the os, whilst the fœtal head was still above the brim. The patient was then told that the treatment rested between embryotomy and Cæsarean section and the possibilities and risks of each were pointed out to her. She said that she would prefer to have a living child if possible but that she would leave the matter entirely in my hands.

Later A.C.E. mixture was administered and on passing the whole hand into the vagina the promontory of the sacrum was felt to make a much greater encroachment on the pelvic space than was at first thought, and the fœtal head was estimated to be considerably larger than is usual. Having *ascertained that the fœtus was alive* it was decided to perform Cæsarean section at once. Sänger's operation was chosen. The placenta was situated in front and was wounded *when the uterine wall was incised but by passing the hand* rapidly down a male fœtus weighing seven and three-quarter pounds was extracted by the neck without any difficulty; the placenta was then rapidly peeled off and all hæmorrhage ceased.

Both mother and child did very well except for some vomiting and severe pain during the first two days on the part of the mother, for which it was found necessary to give morphine, making an uninterrupted recovery and were discharged on July 31st.

NOTE ON A CASE OF CUT THROAT

BY *THE* RIGHT REV. J. E. HINE, D.D. OXON., M.D. LOND.,
BISHOP OF ZANZIBAR.

NOT *long since I sent notes of a case of abnormal delivery* which the Editors of THE LANCET were good enough to insert. Here is another example of the vital energies of primitive man when still unspoilt by modern civilisation. The history of the case is rather vague, but apparently the patient was living by himself in a small village near Magila in German East Africa. During the night a stranger entered the hut and without any apparent reason cut the throat of the sleeping inmate. I happened to be in the neighbourhood and the chief sent for me about 12 hours after the wound was inflicted to see if I could do anything for the relief of the victim. When I reached the place I found a strong young man with a deep and extensive wound across the throat just above the larynx. The air passages were not injured but there had been a great deal of hæmorrhage though the wound did not involve any of the larger vessels. The patient was much exhausted and some oozing of blood was still going on. Native medicines had been applied and I removed a quantity of black gritty material which looked like charcoal with which the wound had been packed. Several vessels had to be tied and the wound after having been cleaned as far as possible was closed with a few sutures and dressed with antiseptic gauze. Treatment of any further kind being impossible in the circumstances I told the people to carry the man to our nearest mission station, a distance of some eight miles, where he could be properly looked after by the nurses resident there. This they did the same night carrying the patient on a native bedstead. The road is very hilly and rough and the jolting caused a recurrence of hæmorrhage, so that he arrived in a state of great prostration. The nurses attended to him according to my directions which followed the usual lines for the treatment of such cases. The man kept quiet during the day, but that same evening the schoolboys happened to be holding a native dance in the quadrangle adjoining the room where the patient was lying. It appears that he was a famous dancer and the sound of the drumming so excited him that, cut throat whether or no, he could not refrain from getting up and in a few minutes he was in the midst of the crowd dancing his hardest, as though nothing of a serious nature was wrong with him. A native African dance involves bodily exercise of considerable vigour and it was not surprising *that after a time the hæmorrhage returned*. But the patient (if that is the right term to use of such a person) notwithstanding went on at his work closely followed up by his nurse who was making efforts to recapture him, until at length he fell down in a semi-fainting condition and was carried back to his bed. I saw him on the next day on my return and found him surprisingly well. The wound healed up rapidly and in about a fortnight he was able to go home.

In the days of my youth one of our professors used to tell us that under certain conditions we should do well "to follow the expectant method of treatment, and perhaps combine it with the exhibition of a placebo." This is the finest description of how to do nothing that the therapeutic mind ever conceived. In Africa it is an excellent method to follow. The expectancy is all on the side of the surgeon as you never know what your patient may choose to do next. And the "placebo" is what the patient pleases rather than his medical attendant. A wise combination of the double method is a sure way to fame if not to fortune.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF SEPTIC MENINGITIS AND HERNIA CEREBRI FOLLOWING COMPOUND FRACTURE OF THE SKULL; RECOVERY.

(Under the care of Mr. R. T. H. BUCKNALL.)

A BOY aged 16 years was on Dec. 30th, 1901, thrown from a runaway horse and pitched head foremost against a rough hewn stone wall. He sustained a compound depressed fracture of the skull in the left parietal region and remained unconscious for 19 hours. Portions of bone and damaged brain were extracted from the wound soon after the accident and a small dressing was fixed on with strapping. 30 hours after the accident he arrived at University College Hospital and was admitted.

On examination the temperature was 101° F. and the pulse was 135 and bounding. The patient lay curled up on his left side, in a drowsy state with limbs flexed and eyes tightly closed. On being roused he would occasionally answer rationally but he usually responded to any interference or questioning by cursing, struggling, and striking out at those who examined him. His condition was typically one of marked cerebral irritation. The right pupil was slightly smaller than the left. There was no paralysis or anæsthesia anywhere. On removing the dressing a ragged and extremely dirty stellate wound of the scalp was exposed, the hair all round being matted with dirt and blood. The wound was about one and a half inches in its longest diameter, which ran obliquely forwards and upwards just below the parietal eminence. In the middle of the gaping wound fragments of bone and disintegrated brain tissue could be detected.

The head was shaved under an anæsthetic, the scalp wound was then found to lie three inches from the saggital suture and three inches behind a vertical line drawn upwards from the anterior margin of the external auditory meatus. After cleaning the scalp a flap was turned down with the wound at its centre, so as to lay bare most of the lower part of the parietal bone in its posterior half. A much depressed and comminuted area of bone was thus exposed one and a half inches long by one inch in breadth with a hole admitting the end of the thumb about its centre through which brain substance was exuding. From the anterior extremity of the depressed area a fissure ran directly forwards across the exposed portion of the parietal bone and apparently continued beneath the unreflected scalp. On removing the whole of the depressed bone, which was much fissured and very grimy, a hole in the dura mater one and a quarter inches long with a cross tear from its centre half an inch long was found. On enlarging this aperture bone and dirt were evident in the lacerated and bloody brain tissue beneath. It was then found that a considerable quantity of blood was lying between the dura mater and bone and also between the dura mater and brain in front of the point of injury and along the line of the fissured fracture in the parietal bone. On removing the clot free hæmorrhage ensued and the bone on each side of the fissure was chipped away, after incising and turning flaps of scalp up and down, in order to reach its source. When sufficient bone had been removed it was found that the hæmorrhage was due to tearing of the middle meningeal artery as it lay in the dura mater opposite the fissure, which crossed the artery at right angles. The ends of the meningeal artery were ligatured. All blood clot was now removed and the torn and dirty edges of the dura mater and scalp were cut freely away. All the damaged brain tissue was also freely removed. The cut margins of the dura mater were united by suture in front, the hiatus behind being left open at the seat of original injury. The scalp flap was reapplied and sutured, a gauze drain being led out of the posterior inferior angle and another out of the hiatus in the scalp, skull, dura mater, and brain resulting from the injury. Towards the end of the operation the pulse showed signs of failing but it rapidly recovered after intravenous injection of two pints of normal saline solution.

Immediately after the operation the temperature rose to 104° and the pulse to 156. Ptosis was present on the right side and the right angle of the mouth was retracted, causing the naso-labial fold to be deeper on this side (right facial spasm). During the same evening and through the night the patient was restless and delirious, continuously talking at random, shouting and spelling words, and repeating letters. No sleep was obtained in spite of bromides and morphine. There were no intervals of consciousness; the urine had to be drawn off. On the next day (Jan. 1st) he was a little quieter and would answer some questions rationally and complained of severe headache. The ptosis was less marked; the right side of the face was no longer retracted but was slightly paralysed instead, the distribution being impossible to detect with certainty. The temperature remained at 102° and the pulse at 120 throughout the day. He had not yet ceased vomiting. On the 2nd he had passed a better night but was still very restless. He became quieter during the day and the temperature fell to 99·2° and the pulse to 100 in the evening. No vomiting had occurred since the previous day. On the 3rd he was much worse. He awoke from a quiet sleep at 5 A.M. and after screaming a fit, commencing in the left arm and spreading to the left and then the right side of the body was observed. During the fit the head and eyes were turned to the left and the left side of the face was contracted. The fit lasted two minutes and consisted of clonic, followed by tonic, contractions. After the fit the left arm was found to be paralysed. The patient vomited with the fit. At 8.15 and 10 o'clock on the same morning two exactly similar fits occurred but consciousness was not lost in the last one. At noon the left arm was only paralysed below the elbow and the right ptosis and right facial paresis were less marked. The patient gradually became more restless and noisy and complained of his head. The temperature varied between 100° and 101° and the pulse remained about 100. Vomiting was now frequent. The reflexes were unaltered. On dressing the wound a hernia cerebri was beginning to project through the aperture caused by the injury and a smaller one protruded through the drainage hole further back. A little pus was oozing through the suture line of the flap so that the stitches were removed and the flap was re-opened. The herniæ were washed with pure alcohol and fomentations were applied to the whole area. On the 4th the condition remained the same; the patient was noisy and semiconscious. On the 5th the temperature rose from 102° to 105° and the herniæ were more prominent. He was even more restless and noisy, rolling about and yelling incessantly and vomiting at frequent and irregular intervals. During the 6th, 7th, and 8th the temperature varied between 103° and 105·4°, the pulse ranging from 105 to 120, and the respirations between 20 and 28. The patient remained very restless all the time but the herniæ cerebri became definitely smaller and the paresis of the left forearm and hand became less marked. The right facial paralysis and ptosis disappeared entirely. On the evening of the 8th the temperature fell to 99° and the pulse to 72. On the 9th the temperature reached 102° in the morning but fell to normal in the evening without any improvement, however, in the patient's mental condition. On the night of the 11th he slept quietly for the first time and was much better on the 12th when the herniæ were so shrunken as no longer to project beyond the skin. No vomiting had occurred since the 7th. From the 12th to the 15th improvement continued, though the temperature still shot up from 99° to 104° every morning. On the 14th advantage was taken of the patient's more calm condition to examine the eyes. The right disc was slightly ill-defined, the left was definitely swollen, and a few small hæmorrhages could be detected in the retina. From the 15th to the 20th the temperature never rose above 100° and afterwards remained normal. Meanwhile the patient gradually became quite rational and slept well, putting on flesh again very quickly. The scalp wounds were rapidly granulating and healing, and all signs of paresis in the left arm disappeared on the 18th. On the 19th the right disc was perfectly normal and the left was clearing rapidly. On the 30th the scalp was healed and he was otherwise well, but a subcutaneous abscess in the abdominal wall near the iliac spine had to be opened and drained. During the ensuing fortnight several similar abscesses formed beneath the skin in other parts. They all gave a growth of staphylococci on cultivation and appeared to be of pyæmic origin. The patient left the hospital at the end of February perfectly well. He has been seen frequently during the last three years and has had no trouble of any kind since his discharge.

Remarks by Mr. BUCKNALL.—The case is of interest for two reasons: (1) it is an example of recovery after the occurrence of symptoms indicating the presence of septic meningitis; and (2) it is an instance of the cure of a hernia cerebri.

As septic meningitis is so invariably fatal it is important in the present case to consider two questions: (1) was general septic meningitis actually present? and (2) if so, can any reason for the unexpected recovery be found?

1. The presence of typical meningitis appears almost certain on account of the character of the temperature, the fits, headache, vomiting, and delirium. It is also indicated by the transient paralysis and the presence of optic neuritis, for it is difficult to account for the combined exhibition of all these symptoms in any other way. It is just possible, however, to regard the fits and paralysis of the arm as due to the injuries just behind the right motor cortex and to regard the ptosis and facial paralysis as the result of hæmorrhage and inflammation extending to the third and seventh nerves on the right side. Even then, however, it would be difficult to assign a cause for the optic neuritis, restlessness, delirium, and vomiting or to explain the continued high temperature in spite of opening up the wound.

2. With regard to the question of recovery, the only cause that can be found for its occurrence is the very free and early drainage afforded by the large opening in the skull and dura mater which had to be made in order to cut away all damaged tissues and to reach the middle meningeal artery. From this aspect the case bears out the suggestion made by Sir Victor Horsley at the International Medical Congress at Berlin in August, 1890, that free drainage was the only treatment for meningitis likely to be successful. It may serve to encourage the adoption of this line of treatment therefore in the otherwise hopeless cases in which symptoms of meningitis have set in.

As an example of success following early interference also it may further serve to point out the advantages of laying open the skull as soon as possible, for it is well known that if septic meningitis is allowed to proceed the results of late operative interference are as disappointing as they are in septic peritonitis in similar circumstances. The advantages of a free opening of the skull and dura mater in these cases are at least two in number: 1. Such an opening tends to diminish the spread and virulence of the septic processes present by affording drainage and avoiding tension of the inflammatory products which would lead to greater local destruction of the parts and to a general rise of intracranial tension. 2. It also tends to prevent or to diminish the rise of intracranial pressure generally by opening the closed cavity of the skull and allowing a temporary protrusion of the swollen contents. In this way a dangerous rise of pressure which would otherwise prove fatal from cerebral anæmia may be tided over

As an instance of the cure of hernia cerebri the case also opens up the question of the correct treatment of this condition, concerning which very little information is to be found in the text books, where the pathology of hernia cerebri is also very imperfectly accounted for

Hernia cerebri occurs in two chief circumstances (1) in the presence of intracranial sepsis due to meningitis local encephalitis, or abscess, and (2) in the presence of tumours or gummata of the brain In each instance an aperture must exist in the skull and dura mater, either as the result of a depressed fracture or the removal of bone by necrosis or operation In tumour or gumma the hernia may occur after trephining whether the growth has been removed or not In abscess it may form even while the abscess is draining thoroughly In most cases, however, in which it occurs with abscess post mortem evidence goes to show that drainage has either been imperfect or else a second unopened abscess has coexisted

The actual causes which lead to the protrusion of the hernia are two in number 1 In all cases there is a rise of intracranial tension, as shown by the flattening of the convolutions at the time of operation the optic neuritis, and the gradual changes in the pupils pulse, respirations and temperature which occur and which are due to pressure anæmia of the brain 2 In some cases there may also be local softening and swelling of the area of the brain which becomes herniated, rendering it more liable to become extruded After the removal of tumours of the brain a transitory hernia may occur It is due to the rise of general tension caused by the injury and hæmorrhage at the time of operation, and also to the congestion which may occur locally in consequence of thrombosis of adjacent cerebral veins After the skull has been opened and a gumma found and left untouched a hernia may occur owing to the general rise of intracranial tension due to the tumour alone It will rapidly subside, however, subsequently if potassium iodide is given as in a case I have observed in which marked optic neuritis and a post operative hernia due to a cerebral gumma disappeared concurrently,

In cases of cerebral abscess complicated by hernia the usual cause which leads to the formation of the hernia and prevents it from subsiding is the rise of intracranial tension resulting from imperfect drainage The difficulty of draining such abscesses with tubes owing to their becoming blocked by the semi diffluent brain substance in a comparatively short time is only too well known and in such cases I should suggest making a large opening in the skull and dura mater and removing a wedge of brain substance so as thoroughly to lay open the abscess cavity and to remove its wall if possible afterwards plugging with gauze from the bottom In a case of temporo sphenoidal abscess in which I adopted this treatment no hernia cerebri formed in spite of the presence of meningitis of the base The latter affection ultimately proved fatal six days after operation, being due to a separate infection resulting from necrosis of the inner wall of the petrous bone which was the seat of advanced disease resulting from otitis

In hernia cerebri accompanying septic meningitis and in local encephalitis due to compound fractures and other
causes rai softening and
œdema of both tend to
produce a to lead to its
subsidence relieved (1)
dura mater,
which can best
s of the large
eral ventricle,
such a hernia
in a boy I observed with a cerebral abscess The abscess was drained but symptoms persisted and a rapidly increasing hernia cerebri appeared A fruitless search for more pus led to the ventricle being tapped and recovery forthwith ensued

For the prevention and treatment of hernia cerebri, therefore, a free opening in the skull and dura mater appears to be necessary in all cases for the following reasons —

1 In cases of *tumour in which the tumour is removed*, to tide over the subsequent period of increased intracranial tension which is liable to occur and to lead to a hernia with dangerous pressure symptoms, if only a small opening is made

2 In cases of tumours which cannot be removed, to relieve tension and thus to prevent the formation of a hernia and also to prevent or to delay the onset of headache, vomiting, and blindness due to optic neuritis which would all rapidly come on if nothing were done or a small opening in the skull were made

3 In cases of abscess to pr

4 In cases of septic meningitis and local encephalitis to afford the only means of reducing the rising intracranial tension and diminishing the virulence of the septic processes present by affording free drainage and a temporary exit for the swollen intracranial contents

The rapid cure of the hernia in the case now recorded can only be ascribed to the free drainage afforded It is probable also that the relief of tension at this period afforded by the large aperture in the skull may also have prevented death from compression

The questions of shaving off the hernia itself or applying lead weights or caustics to it which have frequently been discussed, and which indeed are often the chief details of treatment referred to are of practically no importance as the herniated mass is only the outward sign of the pressure within the skull which is the real source of danger The mass is extracranial and it can do but little harm unless it blocks the whole aperture in the bone and dura mater and so prevents drainage in which case the latter should be removed more widely The recommendation to cut off the hernia to afford drainage because it only consists of granulation tissue and a very slight trace of disintegrated brain tissue is histologically correct but it is based on false surgical principles, as no better drainage is obtained and the hernia rapidly re forms though amputated repeatedly

QUEEN'S HOSPITAL, BIRMINGHAM

A CASE OF RETENTION OF URINE DUE TO THE PRESSURE OF A FIBROID TUMOUR OF THE UTERUS AT THE AGE OF 25 YEARS

(Under the care of Dr C E PURSLOW)

THE patient a single woman, was admitted into the Queen s Hospital Birmingham on Dec 16th, 1903 She stated that she was 25 years of age in the previous September She had always enjoyed good health with the exception of a winter cough Menstruation began at the age of 14 years and had always been regular *the last period occurring a fortnight* before admission The loss had been moderate and the periods had always been attended by pain, there had been no increase in either loss or pain lately Three weeks before admission she found herself unable to pass urine Mr A G O Irvine of Selly Oak was sent for and he passed a catheter, at the same time he made a vaginal examination and detected the presence of a tumour A week later the catheter was required again and subsequently while waiting for admission to the hospital there were further attacks of retention of urine necessitating the use of the catheter on each occasion

On admission the patient was a healthy looking woman except that she had a slight dusky flush on each cheek Examination of the chest showed that the heart was enlarged, the apex beat being displaced outwards and that there was a well marked presystolic thrill with a loud double mitral murmur Nothing could be felt on palpating the abdomen but on making a vaginal examination a smooth rounded mass could be felt filling up the posterior part of the pelvis, bimanually this could be identified as a uterine tumour The sound passed four inches in the normal direction and on the *front aspect of* the tumour Uterine fibroid was diagnosed and the circumstances were held to justify surgical interference

Operation was performed on Dec 19th The abdomen was opened in the middle line and the uterus and tumour were
removed by
removed but
allowed to re
the wound healing by first intention and she has since returned to her situation and is now performing all her duties as formerly There has been no further trouble with micturition

The uterus with the tumour after removal weighed 1 pound 9¼ ounces The tumour was seen to be situated in the posterior wall of the uterus separated by a thin layer of tissue from the uterine cavity, the latter being spread out over its anterior surface. Dr. Stanley Barnes, pathologist to the hospital, kindly made a microscopical examination of the tumour and reported that it was a fibromyoma, containing more unstriated muscular tissue than is usually found in those tumours.

Remarks by Dr. PURSLOW.—The noteworthy point about the case is the age of the patient. So far I have been able to discover only one recorded case in which retention of urine due to the pressure of a uterine fibroid has occurred at so early an age and that is mentioned by Dr. C. J. Cullingworth in a paper entitled "An Analysis of 100 Cases of Uterine Fibromyoma," which appeared in the first volume of the *Journal of Obstetrics and Gynæcology of the British Empire*.

As regards treatment all authorities are agreed that repeated attacks of retention of urine due to the pressure of a uterine fibromyoma are an indication for surgical interference. Hysterectomy was performed in this case as the situation of the tumour and its relation to the uterine cavity appeared to contra-indicate myomectomy.

I am indebted to Mr. Irvine for kindly supplying some of the notes of the case and to Mr. E. L. Clay, obstetric house surgeon, for valuable assistance in its treatment.

Reviews and Notices of Books.

Handbuch der Allgemeinen und Lokalen Anaesthesie für Aerzte und Studierende. (Handbook of General and Local Anæsthesia for Practitioners and Students.) By Professor F. Z. DUMONT of Berne. With 116 illustrations. Berlin and Vienna: Urban and Schwarzenberg. 1904. Pp. 234. Price 7 marks.

Die Chloroform und Aethernarkose in der Praxis. (Chloroform and Ether Narcosis in Practice.) By Dr. KOBLANCK of Berlin. Wiesbaden: J. F. Bergmann. 1904. Pp. 42. Price 1.20 marks.

Professor Dumont's work is divided into three main portions dealing respectively with general anæsthesia by inhalation, general anæsthesia by spinal injection, and local anæsthesia. The book is clearly written but is marred by being too much of a compilation, with too little of the author's own experience and observations. The illustrations are good. Local or regional anæsthesia is very fully dealt with and obviously many substances have been used for this purpose abroad with which we are unfamiliar in this country. Yet their very multiplicity suggests that no one of them has proved to be satisfactory, and, indeed, Professor Dumont's excellent discussion of local and general anæsthesia in comparison shows him to be, generally speaking, an enthusiast for the latter rather than for the former process. In this connexion the tables which he quotes from Mikulicz are deserving of notice. Mikulicz found to his surprise that the occurrence of lung troubles after laparotomy was not in the least affected by employing local instead of general anæsthesia. Only in gastrostomies did there appear to be any difference in favour of the local method. In all other cases results slightly favoured general anæsthesia or were almost the same with the two processes. If other surgeons could repeat Mikulicz's comparison a most important lesson might be learned with regard to those after-effects that are urged as a contra-indication of general anæsthetics in laparotomies. Careful notes, however, must be provided of the nature of the general anæsthetic employed and the method by which it is administered. These are wanting in Mikulicz's tables as quoted by Professor Dumont. The author speaks favourably of ethyl chloride as a preliminary to ether but unfortunately gives no information as to how wide his experience has been of this anæsthetic sequence. "Combined narcosis"—i.e., anæsthesia by means of ether or chloroform preceded by morphine in various forms and combinations—seems to be a very favourite method on the continent. The advantages which Professor Dumont claims are lessened secretion of mucus and the like, prevention of reflex syncope, diminished after-sickness, and great economy of chloroform. He seems to think highly of ethyl chloride and quotes statistics of 16,000 cases with one death. Ethyl bromide he considers a very dangerous anæsthetic. Generally speaking his favourite anæsthetic seems to be a mixture of ether and chloroform in the proportions of 1 to 2 parts.

Dr. Koblanck's little book does not call for much comment. Its scope is, as indicated by the title, strictly limited. Nor is there in it much evidence of experience or of any new observations. Dr. Koblanck prefers to avoid general anæsthetics in face operations, an opinion in which many surgeons will disagree with him. He considers gout a serious contra-indication for ether and chloroform but does not explain why. His consideration of the mental or psychical attitude of the patient in relation to the taking of anæsthetics may be alluded to as being particularly worthy of perusal.

A Text-book of Clinical Anatomy for Students and Practitioners. By DANIEL N. EISENDRATH, A.B., M.D., Professor of Clinical Anatomy in the Medical Department of the University of Illinois, &c. With 155 illustrations. London, Philadelphia, and New York: W. B. Saunders and Co. 1903. Pp. 515. Price 21*s.* net.

Professor Eisendrath's is the latest addition to the number of text-books of applied anatomy of which there has been so plentiful a supply of late years. It is a lavishly illustrated octavo volume of convenient size but of great weight. In the words of the author "its object is to serve as a bridge for both practitioner and student from the descriptive anatomy, as it is usually taught in the first two years of a medical course, to its daily application at the bedside, in the clinic, or in the operating room." We think that Professor Eisendrath has achieved his design and at the same time has succeeded in presenting his matter in an attractive and interesting manner. The arrangement adopted is regional and in dealing with each region the parts to be recognised by sight or touch are first indicated; directions for surface-marking the deeper structures then follow; and finally a short exposition of the main clinical applications of the anatomical facts completes the section.

We have tested the information supplied in many directions and on the whole find it fairly full and accurate. There is nothing of striking novelty to note. There are some points, or rather, we should say, many, which will need amendment in future editions. We will mention a few of these. In Fig. 8, illustrating the relations of the cranial nerves, Meckel's ganglion is misnamed otic. The assertion that the nasal bones reach only to the level of the inner canthus is surely inaccurate. The attribution of stertor to buccinator paralysis ignores the soft palate which is the chief factor. To state that "the aorta reaches the vertebral column on the left side of the upper dorsal vertebra" is not illuminating. The surface marking given for the axillary artery in Fig. 96 is surely incorrect. The caudate lobe of the liver is certainly not the lobe so labeled in Fig. 72. The same figure gives an erroneous idea as to the complexity of the root of the mesentery. The surface relations of the lung in the right axilla as given on p. 153 do not agree with those in the accompanying illustration, which are more correct. The subclavian vein and artery do not lie beneath the pectoralis minor, as stated on p. 154, neither does the brachial plexus lie in front of the subclavian artery (or even in front of the axillary) in its second stage.

We are bound to state, and the few examples quoted above form our justification, that the book shows evidence of want of sufficient revision. This is a great pity as the plan is good and the applications are mostly up to date. The illustration of surface markings by photographs direct from the model has much to recommend it and imparts life to a subject which easily degenerates into a dry repetition of well-worn facts.
